21   **Abstract:**

22   Adverse maternal diets high in saturated fats are associated with impaired neurodevelopment and

23   epigenetic modifications in offspring. Maternal milk, the primary source of early life nutrition in

24   mammals, contains lactation-specific microRNAs (miRNAs). Lactation-specific miRNAs have

25   been found in various offspring tissues in early life, including the brain. We examined the effects

26   of maternal high saturated fat diet (mHFD) on lactation-specific miRNAs that inhibit DNA

27   methyltransferases (DNMTs), enzymes that catalyze DNA methylation modifications, in the

28   amygdala of female offspring during early life and adulthood. Offspring exposed to mHFD showed

29   reduced miR-148/152 and miR-21 transcripts in stomach milk and amygdala in the first week of

30   life. This was associated with increased DNMT1 expression, DNMT activity, and global DNA

31   methylation in the amygdala. In addition, persistent DNA methylation modifications from early

32   life to adulthood were observed in pathways involved in neurodevelopment as well as genes

33   regulating the DNMT machinery and protein function in mHFD offspring. The findings indicate a

34   novel link between exogenous, lactation-specific miRNAs and developmental programming of the

35   neural DNA methylome in offspring.

36

Introduction:

Adverse maternal diets high in saturated fats (mHFD) are associated with impaired neurodevelopment and epigenetic modifications in offspring. Methylation modifications have been reported both globally (Vucetic et al., 2010) and at select candidate genes in the brain of offspring exposed to maternal nutrition stress during perinatal life (Grissom et al., 2014; Marco et al., 2014; Schellong et al., 2019). However, studies to date have largely focused on adult offspring, long after the period of early developmental exposure. Consequently, the gene regulatory mechanisms involved in DNA methylation modifications during the period of exposure to a maternal obesogenic diet and the extent to which these modifications are maintained into adulthood are unknown.

There is recent evidence that the expression of maternal, lactation-specific microRNAs (miRNAs), which mediate gene silencing via post-transcriptional regulation of target mRNAs, is significantly altered by a maternal obesogenic diet (Chen et al., 2017). Lactation-specific miRNAs, encapsulated in stable milk-derived exosomes, appear to cross the offspring's developing intestinal endothelium post-ingestion (Modepalli et al., 2014; Zempleni et al., 2019; Zhang et al., 2012), and have been found in various tissues in offspring during early life, including the brain (Baier et al., 2014; Chen et al., 2016; Izumi et al., 2015; Lässer et al., 2011; Manca et al., 2018). miRNAs belonging to miR-148/152 family are of particular interest, because they are highly expressed in maternal milk (Benmoussa and Provost, 2019; Van Herwijnen et al., 2018) and are known regulators of DNA methyltransferases (DNMTs), enzymes that catalyze DNA methylation modifications. *In vitro* studies have shown that miRNA-148a and miRNA-152 directly target and inhibit DNMT1 translation (Long et al., 2014; Pan et al., 2010; Wang et al., 2014; Xu et al., 2013).

63   miRNA-21 is also abundant in maternal milk and indirectly inhibits DNMT1 translation by

64   targeting Ras guanyl nucleotide-releasing protein-1 (RASGRP1) (Pan et al., 2010).

65   Here, we examined the relationship between lactation-specific miRNAs, the enzymatic

66   machinery responsible for DNA methylation modifications, and programming of the DNA

67   methylome in female Long-Evans rat offspring exposed to mHFD. We found that exposure to

68   mHFD altered levels of lactation-specific miRNA in stomach milk and the brain (amygdala) during

69   the first week of life. These changes in miRNA levels were inversely associated with DNMT

70   transcriptional and enzymatic activity. Correspondingly, mHFD offspring showed lower levels of

71   global DNA methylation and locus-specific DNA methylation modifications, some of which

72   appear to persist to adulthood.

73

74   **Results**

75   **Dam and Offspring Body Weight**

76   mHFD dams consuming HFD for 4 weeks were significantly heavier than mCHD dams at

77   conception ($t(1,14) = 2.91$, p=0.01). During gestation, the caloric intake was significantly higher

78   among mHFD dams compared to mCHD dams ($t(1,14) = 3.29$, p=0.005). There were no

79   differences in offspring body weight across the two diet groups at birth (p>0.05) and all pups

80   increased in weight during the pre-weaning period ($F(1,13)= 953.7$, p<0.01). At postnatal day 7

81   (P7), offspring exposed to mHFD (18 ± 0.72 g) were heavier relative to mCHD offspring ($16 \pm$

82   0.38 g; Bonferroni post-hoc p=0.006). In data reported previously, body weight and caloric intake

83   for dams and their offspring sacrificed in adulthood for this study, showed similar effects of mHFD

84   during the pre-weaning period (Sasaki et al., 2013). At P90, offspring showed comparable body

85   weights among the two diet groups (p>0.05).

86 **Expression of maternal milk-derived miRNAs in stomach milk and amygdala**

87 At P7, miR-152-5P (t(1,6)=6.393, p=0.001) and miR-21-5P (t(1,6)=4.15, p=0.006) showed

88 lower transcript abundance in the stomach milk of female neonates exposed to mHFD, whereas

89 expression levels of miR-148-5P (t(1,6)=-0.056, p=0.957), miR-148-3P (t(1,6)=-1.751, p=0.131),

90 and miR-152-3P (t(1,6)=-0.042, p=0.968) remained unchanged (Fig.1A). For the same five

91 miRNAs measured in the female amygdala, miR-148-3P (t(1,12)=2.293, p=0.041) and miR-152-

92 3P (t(1,12)=2.254, p=0.048) decreased in transcript abundance in response to mHFD when

93 compared to mCHD (Fig. 1B). miR-148-5P (t(1,12)=0.911, p=0.380) and miR-152-5P

94 (t(1,12)=0.049, p=0.962) remained unchanged and miR-21-5P was not detected in the amygdala
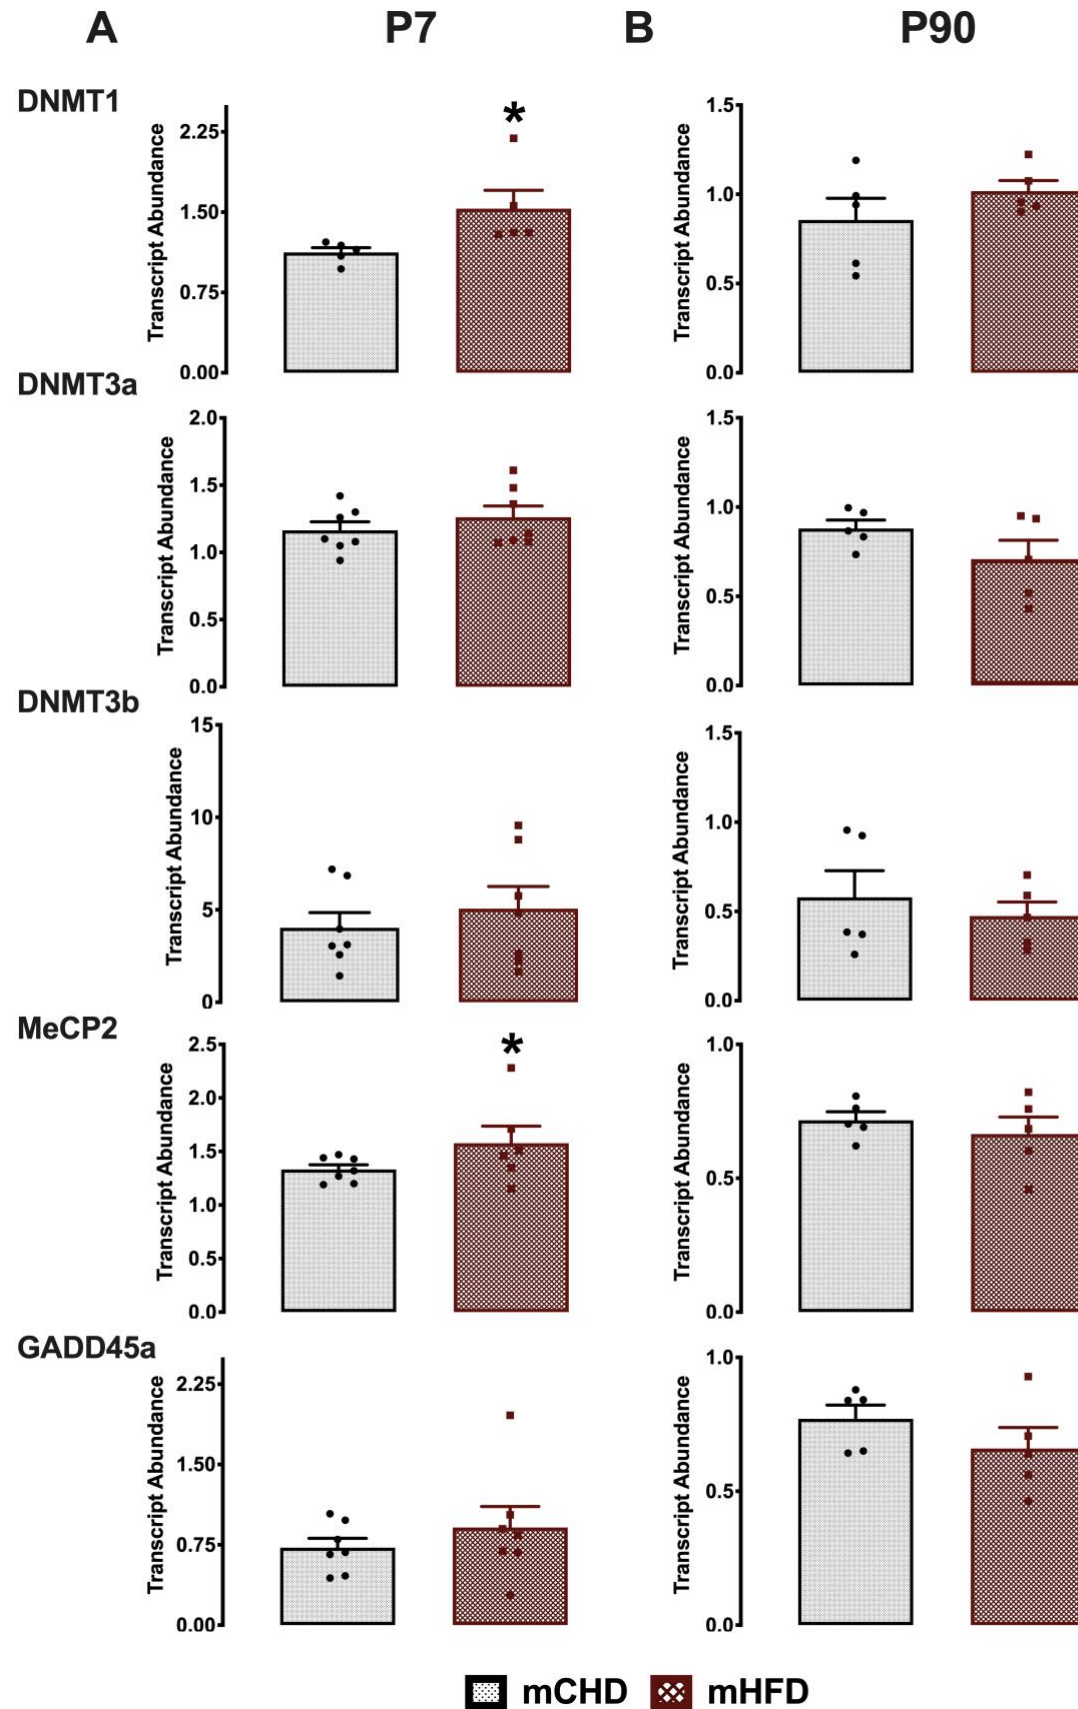

95 of female offspring at P7.

96 **mRNA expression of epigenetic regulators**

97 We examined the mRNA transcript abundance of epigenetic regulators involved in DNA

98 methylation modifications, including DNMT1, DNMT3a, DNMT3b, direct post-transcriptional

99 targets of lactation-specific miR-148/152 and miR-21, as well as MeCP2 and GADD45α in the

100 amygdala of female offspring exposed to mCHD and mHFD at P7 and P90. DNMT1 (t(1,10)=-

101 2.346, p=0.041) and MeCP2 (t(1,10)=-2.237, p=0.049) transcript abundance significantly

102 increased in response to mHFD at P7 (Fig. 2A). Transcript abundance of DNMT3a (t(1,12)=-

103 0.942, p=0.365), DNMT3b (t(1,12)=-0.712, p=0.490), and GADD45α (t(1,12)=-0.871, p=0.401)

104 remained unchanged. At P90, transcript abundance of DNMT1 (t(1,8)=-1.20, p=0.265), DNMT3a

105 (t(1,8)=1.482, p=0.177), DNMT3b (t(1,8)=0.623, p=0.551), MeCP2 (t(1,8)=0.724, p=0.490), and

106 GADD45α (t(1,8)=1.186, p=0.270), remained unchanged (Fig. 2B).

125

**DNMT Enzymatic Activity and Global DNA Methylation**

We next examined whether changes in transcript abundance of DNMTs was associated with changes in their enzymatic activity and global LINE-1 5-methylcytosine (5mC) levels. In P7 offspring, DNMT enzymatic activity robustly increased in response to mHFD ($t(1,5)$=-5.95, p=0.02; Fig. 3A). Correspondingly, global LINE-1 5mC (%) increased in response to mHFD when compared to mCHD ($t(1,6)$=-2.98, p=0.03; Fig. 3B). A strong linear correlation was observed between increased DNMT enzymatic activity (OD/h/mg) and increased global LINE-1 5mC (%) levels at P7 ($R_2 = 0.896$, $p= 0.001$; Fig. 3C).

At P90, female mHFD offspring had a trend of lower DNMT enzymatic activity compared to mCHD ($t(1,6)= 1.794$, $p = 0.06$; Fig. 4A). Global LINE-1 5mC (%) levels significantly decreased in response to mHFD ($t(1,6)$=3.805, p=0.009; Fig. 4B). However, global LINE-1 5mC (%) was not associated with total DNMT enzymatic activity at P90 ($R_2 = 0.07$, $p= 0.538$; Fig. 4C).

Genome-wide DNA Methylation Analysis

Genome-wide DNA methylation at single nucleotide resolution was assessed using reduced representation bisulfite sequencing (RRBS). At P7 and P90, female offspring showed 777 and 1050 significant differentially methylated regions (DMRs), respectively. At P7, 69% of DMRs were hypomethylated and 31% were hypermethylated, and at P90 61% of DMRs were hypomethylated and 39% were hypermethylated (Fig. 5A). At P7, approximately 50% of DMRs were found in intergenic regions, while 21 % and 29 % were found in promoters and gene bodies, respectively. At P90, 56% of DMRs were found in intergenic regions, while only 6% were found in promoters and 38% were found in gene bodies.

Fifty-seven DMRs were shared across the two age groups (Fig. 5B) corresponding to 26 genes (Table 1). Fifteen of these genes were consistently hypomethylated at both P7 and P90

177 **offspring exposed to maternal HFD at P7 and P90.** A) Distribution of hyper- and

178 hypomethylated DMRs in HFD offspring in terms of genic location including promoter regions,

179 gene body, and intergenic regions. B) Venn diagram illustrating the number of DMRs that are

180 unique to female offspring at P7 (blue) and P90 (green) in response to maternal HFD exposure in

181 the amygdala. The area in between represents the numbers of overlapping DMRs across the two

182 ages.

183

12

184 (LOC310926, Tbc1d10b, Paqr6, Rgs3, Unc79, Icam4, Gtf2e1, Hic2, Tpst2, Rab5a, Nfatc1, Nhs,

185 Lancl3, Mecp2, Ndufb1), while five genes remained hypermethylated at the two ages

186 (LOC499742, Anxa6, Plvap, Rsu1, Zfp423). Seven DMRs that were hypomethylated and 12

187 DMRs that were hypermethylated in response to mHFD at P7 (33% of the overlapping DMRs)

188 showed opposite methylation differences at P90. The 6 genes associated with these DMRs showed

189 opposite methylation patterns in early life compared to adulthood. Three genes were

190 hypomethylated at P7 and hypermethylated at P90 (Polr3g, Prpf38b, and Htatsf1) and another 3

191 genes were hypermethylated at P7 and hypomethylated at P90 (Ank1, Dupd1, and Tmprss9). A

192 total of 372 and 444 genes were found to be differentially methylated at P7 and P90, respectively

193 (Supplementary Table 2-3).

194 **Gene Annotation Enrichment Analysis**

195   gProfiler was used to conduct Gene Ontology (GO) analysis to identify enriched biological

196 processes associated with the differentially methylated genes. Thirty-four significantly enriched

197 overlapping GO terms were shared across early life and adulthood, clustered into 5 functionally

198 related groups (Fig. 6; Supplementary Table 4). P7 and P90 animals shared GO terms associated

199 with cellular morphogenesis and organism development (10 GO terms) as well as neuronal

200 projection and nervous system development (11 terms). In addition, terms associated with protein

201 phosphorylation (5 GO terms) and protein transportation and secretion (8 GO terms) were shared

202 across P7 and P90. The lipid response GO term was uniquely shared across both age groups and

203 did not cluster with other GO terms.

204   At P7, a total of 372 DMRs were associated with annotated genes. gProfiler identified 163

205 significantly enriched biological processes that clustered into 10 functionally related groups (Fig.

206 7; Supplementary Table 5). Three groups were involved in systems development, consisting of

207 processes related to organismal (8 GO terms), cellular (19 GO terms), and neuronal (27 GO terms)

208 **Table 1.** Genes containing significant DMRs sorted by chromosomes, percentage of differential

209 methylation between mCHD and mHFD, and the location of the DMR in the amygdala of female

210 offspring at P7 and P90.

212

213   development. Two other groups were involved in post-translational modifications, including

214   protein phosphorylation (13 GO terms) and catabolic process (29 GO terms). GO terms involved

215   in cellular responses to stimuli (13 GO terms), including growth factors, stress, and organic

216   compounds, as well as GO terms involving cell secretion and signal transduction (23 GO terms),

217   metabolic regulation (11 GO terms), apoptosis (7 GO terms), and gene expression (13 GO terms)

218   were also enriched in early life (FDRs<0.05).

219   At P90, a total of 444 DMRs were associated with annotated genes, where 105 GO terms

220   were clustered into 7 functionally related groups (Fig. 8; Supplementary Table 6). Three groups

221   were involved in systems development, including organismal (12 GO terms), cellular (14 GO

222   terms), and neuronal (19 GO terms) development. Twenty-four GO terms were clustered into

223   protein phosphorylation and signaling pathways, which included GTPase activity, regulation, and

224   intracellular signal transduction. Twenty-one GO terms were clustered into protein localization

225   and secretion and 10 GO terms were clustered into ion transport. Terms involved in cellular

226   stimulus response (5 GO terms) and the response to lipopolysaccharide and lipids were also

227   enriched in adulthood (FDRs<0.05). DAVID analysis generated a similar list of enriched GO terms

228   that were shared across early life and adulthood as well as GO terms that are unique to each age

229   (Supplementary Fig. 1-3).

230   Gene enrichment analysis was conducted using the Kyoto Encyclopedia of Genes and

231   Genomes (KEGG) database of pathways representing both empirical and predicted molecular

232   interactions, to examine networks that include cellular processes, organismal systems,

233   environmental information processing, and metabolism. Eight KEGG pathways were shared

234   across P7 and P90 age groups, including MAPK, cGMP-PKG, cAMP, and calcium signaling

235   pathways (FDR<0.05; Table 2). These signaling pathways are involved in axon guidance, which

236   was also enriched with a large number of differentially methylated genes. In addition, the oxytocin-

237   signaling pathway, tight junction, and circadian entrainment KEGG pathways were significantly

238   enriched from early life to adulthood.

239   Ten KEGG pathways were unique to early life (FDR<0.05; Supplementary Table 7),

240   including the Wnt signaling pathway, neurotrophin signaling pathway, MAPK signaling, axonal

241   guidance, and long-term potentiation. In addition, two endocrine system pathways including

242   thyroid hormone and GnRH signaling were enriched with genes differentially methylated at P7.

243   KEGG pathways associated with human diseases affecting the nervous system, including

244   Alzheimer's disease and amphetamine addiction, and nervous system related signaling pathways

245   involved in retrograde endocannabinoid signaling were also identified.

246   Twenty KEGG pathways were unique to adulthood (FDR<0.05; Supplementary Table 8).

247   A set of three interrelated signaling pathways were enriched at P90, including the Ras, Rap1, and

248   PI3K-Akt signaling pathways. Three nervous system-specific pathways were enriched including,

249   GABAergic synapse, glutamatergic synapse, and long-term depression. The analysis revealed

250   three endocrine-related pathways, including insulin secretion, relaxin signaling, and aldosterone

251   synthesis and secretion. Two pathways important for cellular integrity, extracellular matrix

252   (ECM)-receptor interaction and focal adhesion, were also identified. A number of cardiovascular

253   pathways relating to cardiomyopathy and vascular smooth muscle contraction as well as pathways

254   involved in cancer development and transcriptional dysregulation were enriched at P90.

Discussion

In this study, we examined the effects of mHFD exposure on lactation-specific miRNAs that inhibit DNMTs, as well as changes in genome-wide DNA methylation modifications in offspring in early life and adulthood. Members of the lactation-specific miR-148/152 family and miR-21 exhibited decreased abundance in ingested stomach milk and the amygdala of mHFD offspring in early life. Correspondingly, we observed increased transcript abundance of DNMT1 and MeCP2 in response to mHFD in neonates. Total DNMT enzymatic activity and global LINE-1-5mC (%) levels also increased in the amygdala in early life, but not in adulthood. Genes regulating the DNMT machinery as well as neurodevelopment were differentially methylated across the two ages.

Female pups exposed to mHFD showed a reduction in miR-152-5P and miR-21-5P in their stomach milk (Fig. 1A) and a reduction in miR-148a-5P and miR-152-3P levels in the amygdala during early life compared to mCHD offspring (Fig. 1B). These findings support previous research indicating that lactation-specific miRNAs belonging to miR-148/152 family survive the digestive tract (likely encapsulated in stable milk-derived exosomes), are absorbed across offspring's intestinal barrier, and are subsequently transported to target neural tissues in rodents. Indeed, several previous studies have shown that milk-derived exosomes survive degradation in the GI tract (Benmoussa et al., 2016; Izumi et al., 2015, 2012; Zhou et al., 2012) and can be absorbed across the intestinal barrier (Modepalli et al., 2014), especially during early life when gut permeability is high (Gareau, 2011). Milk-derived exosomes have also been shown to successfully cross the blood brain barrier of the recipient and have unique distribution patterns (Chen et al., 2016; Manca et al., 2018). Interestingly, several studies have failed to detect endogenously produced miR-148/152 family in peripheral organs including the liver and heart and

24

310   in several regions of the CNS, including cerebellum, thalamus, hippocampus, and spinal cord of

311   adult rats using time dependent expression profiles generated from small RNA sequencing and

312   microarray analyses (Izumi et al., 2014; Minami et al., 2014; Smith et al., 2016). Although we

313   cannot definitively rule out endogenous expression of the miRNAs examined in this study, our

314   findings are consistent with evidence that these miRNAs are likely of maternal origin and are

315   transferred via milk during early life (Alsaweed et al., 2016; Manca et al., 2018).

316   We found a strong inverse correlation between levels of lactation-specific miRNAs and

317   DNMT expression, where miR-148/152 and miR-21 levels decreased, while DNMT1 and MeCP2

318   levels increased in the amygdala in early life among mHFD offspring (Fig. 2A). These findings

319   concur with other studies showing post-transcriptional regulation of DNMT1 by the miR-148//152

320   family. For example, increased expression of miR-152 during lactation in dairy cows has been

321   linked to a marked reduction of DNMT1 mRNA and protein expression in mammary glands

322   (Wang et al., 2014). This reduction is associated with a decrease in global DNA methylation in

323   bovine mammary glands. Likewise, a strong inverse relationship was previously shown between

324   miR-148a and miR-21 and DNMT1 expression in bovine maternal epithelial cell culture (Long et

325   al., 2014; Pan et al., 2010; Xu et al., 2013). In human milk, miR-148a has also been shown to

326   downregulate the expression of DNMT1 *in vitro* (Golan-Gerstl et al., 2017). DNMT1 is known to

327   recruit MeCP2 to methylated loci, inducing transcriptional repression (Chen et al., 2015).

328   Interestingly, our data also show evidence of increased expression of MeCP2 (Fig. 2A) that is

329   positively associated with increased DNMT1 levels and inversely associated with miR-148/152

330   transcript levels. Further, in silico analysis has predicted MeCP2 to be a direct post-transcriptional

331   target of miR-152-3P, however to our knowledge there is no experimental evidence confirming

332   this prediction to date (Ehrhart et al., 2016; www.targetscan.org).

333   DNMT expression in offspring is known to be responsive to changes in the maternal

334   nutritional environment. For example, maternal dietary protein restriction was associated with a

335   decrease in DNMT1 expression in the liver of adult offspring (Lillycrop et al., 2007), and mHFD

336   consumption was associated with a decrease in DNMT3a expression in the hippocampus of fetal

337   male rats (Glendining et al., 2018). Similarly, we found that transcript abundance of DNMT1 in

338   the amygdala was sensitive to changes in maternal diet during early life. However, in adulthood

339   transcript abundance of DNMTs and other epigenetic regulators remained unchanged between diet

340   groups (Fig. 2B). Notably, the increase in DNMT1 and MeCP2 expression in early life in the

341   amygdala was associated with a robust increase in DNMT enzymatic activity (Fig. 3A) and global

342   LINE-1 DNA methylation (Fig. 3B). It has been reported that DNMT1 and MeCP2 form a complex

343   on hemimethylated DNA to regulate DNMT activity (Kimura and Shiota, 2003). The strong

344   association between reduced miR-148/152 levels with increased expression of DNMT1 and

345   MeCP2, combined with increased DNMT enzymatic activity and global DNA methylation suggest

346   a mechanism by which mHFD exposure may program the DNA methylome of offspring during

347   early life, and an important regulatory role for lactation-specific miR-148/152 in this process.

348   We also examined whether changes in DNA methylation patterns we observed during early

349   life were maintained into adulthood, long after the period of mHFD exposure. In adulthood,

350   DNMT enzymatic activity showed a decreasing trend (Fig. 4A), along with a significant reduction

351   in global DNA methylation levels in offspring exposed to mHFD (Fig. 4B). These findings support

352   previous reports showing persistent global DNA hypomethylation in adult offspring exposed to

353   mHFD (Carlin et al., 2013; Vucetic et al., 2010).

354   Next, we examined genome-wide DNA methylation patterns at single nucleotide resolution

355   using RRBS. Over 60% of mHFD-associated DMRs showed hypomethylation and approximately

356   50% were found in intergenic regions (Fig. 5A). Notably, the proportion of DMRs found within

357   promoter regions was substantially higher in early life (21%) compared to adulthood (6%). It is

358   possible that this higher proportion of differential DNA methylation in promoters may be linked

359   to the rapid neurodevelopmental processes that are taking place during the first week of postnatal

360   life. Earlier studies have reported unique temporal patterns of DNA methylation modifications in

361   the brain during perinatal life, where a reversal in the direction of genomewide methylation occurs

362   from prenatal to postnatal development (Lister et al., 2013; Numata et al., 2012). In particular,

363   global methylation levels were shown to decrease during prenatal life and increase postnatally

364   (Numata et al., 2012). However, it should be noted that P7 animals in this study were still under

365   the direct influence of the mHFD and its associated metabolic milieu, conditions that were not

366   present in adulthood, as the animals were weaned onto a control diet. Interestingly, we found that

367   exposure to mHFD during perinatal life also lead to increased global LINE-1 methylation in the

368   amygdala (see Fig. 3B). Taken together, our data suggest an increased period of sensitivity of the

369   neural DNA methylome to dietary stress in early life.

370   We found a total of 57 shared DMRs in both early life and adulthood (Fig. 5B),

371   corresponding to 26 genes annotated to these regions (Table 1). Interestingly, the promoter region

372   of MeCP2 was hypomethylated in response to mHFD across both ages (Table 1); we also observed

373   an increase in the relative transcript abundance of MeCP2 in early life (see Fig. 2A). Indeed,

374   studies have shown that methylation of CpG sites of six previously characterized *cis* regulatory

375   sequences, which are found in MeCP2 promoter and intron 1, is inversely correlated with MeCP2

376   transcript abundance level (Liyanage et al., 2019; Olson et al., 2014). In contrast to early life,

377   MeCP2 transcript abundance in adulthood remained unchanged between offspring exposed to

378   mHFD and mCHD (Fig. 2B), despite the apparent maintenance of promoter hypomethylation

379   among mHFD offspring. These findings suggest an alternate mode of transcriptional control of

380   MeCP2. Post-transcriptional regulation of MeCP2 by polyadenylation and a number of micro-

381   RNAs during development has been reported (McGowan and Pang, 2015; Samaco et al., 2004).

382   Polyadenylation of MeCP2 transcript results in a longer 3'UTR that has been shown to be highly

383   expressed in the brain at birth, decrease progressively during postnatal development, and increase

384   again in adulthood, regulated by RNA-binding proteins and mirco-RNAs (McGowan and Pang,

385   2015; Rodrigues et al., 2016; Samaco et al., 2004).

386   MeCP2 is associated with the regulation of differentially expressed genes in offspring

387   exposed to mHFD. For example, mHFD exposed animals show reduced μ-opioid receptor

388   transcript abundance, promoter hypermethylation, and increased recruitment of MeCP2 to the μ-

389   opioid receptor promoter in reward-related brain regions, including the ventral tegmental area,

390   prefrontal cortex, and nucleus accumbens (Vucetic et al., 2011). In addition, MeCP2 is known to

391   regulate the expression of brain-derived-neurotrophic factor (BDNF) in a dynamic mechanism that

392   could either repress or activate its expression (reviewed in Li and Pozzo-Miller, 2014). Studies

393   have shown a reduction in BDNF transcript levels in several brain regions including the prefrontal

394   cortex, hippocampus, and hypothalamus in developing animals exposed to mHFD (Bae-Gartz et

395   al., 2019; Rincel et al., 2016; Tozuka et al., 2009). It is possible that DNA methylation

396   modifications and changes in transcript abundance in MeCP2 in response to mHFD are involved

397   in the differential gene expression reported in the brains of mHFD offspring.

398   We identified overlapping GO terms (Fig. 6; Supplementary Table 4) and KEGG pathways

399   (Table 2) that were enriched with differentially methylated genes in early life and adulthood to

400   contextualize differentially methylated genes associated with mHFD exposure. GO terms

401   associated with the development of the nervous system (i.e. neurogenesis, neuron development,

402   and nervous system development) and neuronal projections (i.e. neuron projection morphogenesis,

403   axonogenesis, plasma membrane bounded cell projection organization), as well as axon guidance

404   KEGG pathway were highly enriched with genes annotated to DMRs in early life and adulthood.

405   Several earlier studies have reported altered neuronal morphology in brain limbic regions with

406   exposure to mHFD. Specifically, new hippocampal neurons exhibit impaired dendritic

407   arborization in young mice (P35) exposed to mHFD, which was associated with reduced BDNF

408   and impaired spatial learning (Tozuka et al., 2009). Another study showed that mHFD is associated

409   with reduced dendritic length and complexity in the hippocampus and amygdala of adult rat

410   offspring (Janthakhin et al., 2017). Young and adult mouse offspring exposed to mHFD exhibit

411   reduced stability and loss of dendritic spines (Hatanaka et al., 2015). Taken together, our finding

412   may implicate DNA methylation modifications in these effects, though this remains to be

413   examined more in detail.

414   The enrichment analysis also identified age-specific GO terms and KEGG pathways

415   (Fig. 7-8; Supplementary Table 7-8). In early life, GO terms and KEGG pathways involving

416   neuronal development, such as axon guidance, Wnt signaling, neurotrophin signaling and thyroid

417   hormone signaling pathways were enriched with DMRs. Interestingly, previous studies have

418   linked changes in thyroid hormone levels and genes involved in thyroid synthesis to mHFD

419   exposure in offspring across several species, including humans, rodents, (Kahr et al., 2016;

420   Tabachnik et al., 2017) as well as primates (Suter et al., 2012). In particular, thyroid hormone

421   levels and the genes that mediate thyroid hormone synthesis decreased in the hypothalamus and

422   thyroid gland in human fetuses that were exposed to an obesogenic maternal environment (Suter

423   et al., 2012). Our findings implicating DNA methylation modifications in thyroid hormone

424   signaling pathways thus warrant further investigation. In adulthood, glutamatergic and

425   GABAergic KEGG pathways were enriched with genes annotated to DMRs (Supplementary Table

426   8). Anxiety-like behaviour is a well-characterized outcome of dysregulation in glutamatergic and

427   GABAergic systems, and these findings concur with previously published studies showing

428   heightened anxiety-like behaviours in mHFD offspring (Bilbo and Tsang, 2010; Peleg-Raibstein

429   et al., 2012; Sasaki et al., 2013).

430   **Conclusion**

431   Maternal milk is a primary source of nutrition in early life in mammals, and plays an

432   important role in growth, neurodevelopment, immunity, microbiome composition, and behaviour

433   (Andreas et al., 2015; Bagnell and Bartol, 2019; Ballard and Morrow, 2013; Boquien, 2018; De

434   Leoz et al., 2015; Der et al., 2006; Dettmer et al., 2018; Gareau, 2011; Hamosh, 2001).

435   Collectively, our findings suggest a role for lactation-specific miRNAs in neurodevelopmental

436   programming of the DNA methylome by mHFD. With the significant rise worldwide in the

437   number of women of reproductive age who are overweight or obese, understanding the role of

438   miRNA transfer via maternal milk during early development may help identify mechanisms that

439   lead to adverse health outcomes in children, and ultimately enable preventive and therapeutic

440   interventions to support offspring health.

441

442   **Materials and Methods**

443   **Animal Treatment and Handling**

444   Adult female Long Evans rats (7 week) were purchased from Charles River, Canada (St.

445   Constant, QC) and housed with same sex pairs until mating and maintained on a 12:12 - h light–

446   dark cycle (lights on 7:00 am–7:00 pm) with *ad libitum* access to food and water. Females were

447   maintained on either house chow diet (mCHD; 5001; Purina Lab Diets, St. Louis, MO, USA)

448 consisting of 28.5 % protein, 13.5 % fat, and 58 % carbohydrate, or a high fat diet (mHFD;

449 D12492; Research Diets Inc. New Brunswick, NJ, CA), consisting of (by kcal): 20 % protein,

450 60 % fat, 20 % carbohydrate) 4 weeks prior to mating, during gestation, and lactation (Abuaish et

451 al., 2018; Sasaki et al., 2014, 2013). Mating was conducted over a one-week period and sperm

452 plugs were checked twice a day to determine the onset of pregnancy. Females were then separated

453 from males and singly housed throughout pregnancy. After parturition, dams were moved into

454 clean cages and offspring were weighed and culled to 12 pups / litter (6 males and 6 females) when

455 possible.

456 At sacrifice, female P7 neonates were individually removed from their litters, rapidly

457 decapitated; brains and curd stomach milk were collected. Female P90 adults were sacrificed by

458 CO_2 inhalation followed by decapitation to collect brains. Separate litters of animals were used for

459 the various assays: n=4 animals (1/litter/diet group) for LINE-1, DNMT activity, and qPCR

460 analyses at P7; n=4 animals (1/litter/diet group) for RRBS and qPCR analyses at P7; n=4 animals

461 (1/litter/diet group) for milk miRNA analysis at P7; n=4-6 (1/litter/diet group) for LINE-1, DNMT

462 activity and qPCR analyses at P90; and n=4 (1/litter/diet group) for RRBS analysis at P90. Brains

463 obtained from all animals were flash frozen in isopentane and dry ice and stored at -80 °C for later

464 usage. Brains were cryosectioned into 50 µM sections using Research Cryostat Leica CM3050 S

465 (CM3050 S; Leica Biosystems, Concord, ON, CAD) and the amygdala was microdissected using

466 stereotaxic coordinates (P7: bregma: -0.20mm to -1.60 mm (Paxinos et al., 1991); P90 bregma:

467 −1.72mmto −3.00mm (Paxinos and Watson, 2007).

468 We focused on female offspring in this study for several reasons. First, earlier

469 investigations found greater transcriptional differences in the brains of female offspring compared

470 to male offspring exposed to mHFD in early life (Abuaish et al., 2018; Barrand et al., 2017; Sasaki

31

471 et al., 2014) and in adulthood (Sasaki et al., 2013). Second, adult female offspring showed stronger

472 behavioral and physiological alterations in response to mHFD, in comparison to male littermates

473 (Sasaki et al., 2013). These alterations were associated with pronounced changes in gene

474 expression in the amygdala (Sasaki et al., 2013).

475 All experimental protocols were approved by the Local Animal Care Committee at the

476 University of Toronto, Scarborough, and were in accordance with the guidelines of the Canadian

477 Council on Animal Care.

478 **RNA Extraction from Stomach Milk and Amygdala**

479 Total RNA, >18 nucleotides, was purified from curd stomach milk collected from P7

480 offspring that were exposed to mCHD (n=4) or mHFD (n=4) using a combination of QIAzol and

481 miRNeasy Mini Kit (217004; Qiagen, Toronto, ON, CA) as described previously (Izumi et al.,

482 2014, 2013). RNA was extracted from the amygdala of female offspring at P7 and P90

483 (n=6/mCHD, n=6/mHFD) using TRIzol Reagent (15596018; ThermoFisher Scientific, Ottawa,

484 ON, CAD) according to manufacturer's instructions. RNA concentration and quality were

485 measured using a Nanodrop Spectrophotometer (ND-2000C; ThermoFisher Scientific) and

486 RapidOut DNA Removal Kit (K2981; ThermoFisher Scientific) was used to remove sources of

487 genomic DNA contamination. The samples were stored at -80 °C for future use.

488 **miRNA Primer Design**

489 miRNA-specific forward primers for miR-148-5P, 148-3P, 152-5P, 152-3P, and miR-21-

490 5P were designed using annotated mature miRNA sequences obtained from miRBase (Kozomara

491 and Griffiths-Jones, 2011) for *Rattus norvegicus,* using a protocol previously described (Biggar et

492 al., 2014). All miRNA targets were quantified in conjunction with a universal reverse primer

493 (Supplementary Table 1) and a miRNA target-specific forward primer (Supplementary Table 1).

494   Four reference genes (U6 snRNA, 5S rRNA, Snord 96a, and Snord 95a) were tested to determine

495   a set of most stable internal controls to be used for data normalization (Supplementary Table 1).

496   Sequences for the internal reference genes, were based on previously published work on rodent-

497   specific miRNA regulation in the brain (Eacker et al., 2011; Minami et al., 2014).

498   **miRNA Expression Analysis by RT-qPCR**

499   125 ng of total RNA extracted from curd stomach milk and 1 μg of total RNA extracted

500   from the amygdala of the same animals at P7 were processed for miRNA analysis as previously

501   described (Biggar et al., 2014, 2011). miRNA levels in stomach milk and amygdala of P7 offspring

502   were quantified using a StepOne Plus real-time thermocycler with Fast SYBR Green PCR master

503   mix (4385612; Applied Biosystems, Foster City, CA, USA) using a previously established

504   protocol (Biggar et al., 2014). A melt curve analysis was done following each RT-qPCR reaction

505   to ensure that miRNA primers did not yield multiple PCR products.

506   Five lactation-specific miRNAs were quantified in ingested stomach milk (miR-148-5P,

507   miR-148-3P, miR-152-5P, miR-152-3P, and miR-21-5P) and four of the same miRNAs were

508   quantified in the amygdala at P7 (miR-148-5P, miR-148-3P, miR-152-5P, and miR-152-3P;

509   Supplementary Table 1). miR-21-5P was below the detectable range by RT-qPCR in the amygdala

510   at P7. miRNA quantification was done using $\Delta\Delta C_q$ method and all targets were normalized against

511   the GEOmean of two internal reference genes. U6 snRNA and 5S rRNA were determined to be

512   suitable internal controls for both stomach milk and amygdala datasets by NormFinder software

513   (Andersen et al., 2004). Relative miRNA levels were denoted as mean ± SEM representing n=4

514   (stomach milk) and n=6 (amygdala) biological replicates per experimental condition and three

515   technical replicates per biological replicate. Significant differences across mCHD and mHFD

516   exposures were measured using an independent sample Student's t-test with a 95 % confidence

517   interval (p<0.05).

518   **mRNA Expression Analysis by RT-qPCR**

519   Gene expression levels of DNMT1, DNMT3a, DNMT3b, MeCP2, and GADD45 were

520   measured using a StepOne Plus real-time thermocycler with a Fast SYBR Green PCR master mix

521   (4385612; Applied Biosystems) in the amygdala during early life and adulthood. A melt curve

522   analysis was done following each RT-qPCR reaction to ensure that primers did not yield multiple

523   PCR products. Primers (Supplementary Table 1) were designed using nucleotide sequence

524   information available at the National Center for Biotechnology Information (NCBI):

525   www.ncbi.nlm.nih.gov and previously published research (Sasaki et al., 2014, 2013).

526   mRNA quantification was determined using a standard curve consisting of 11 serial

527   dilutions ranging from 500 to 0.49 ng/µL. Quantity means of each target was normalized against

528   the GEOmean of four reference genes, YWAZ, GAPDH, 18s, and Actin B. These four reference

529   genes were determined to be suitable internal controls in the female amygdala during early life and

530   adulthood by NormFinder Software (Andersen et al., 2004). Relative gene expression levels were

531   denoted as mean ± SEM representing n=6 biological replicates per experimental condition and

532   three technical replicates per biological replicate. Significant differences across mCHD and mHFD

533   exposures were measured using an independent sample Student's t-test with a 95 % confidence

534   interval (p<0.05).

535   **Protein Extraction**

536   Total soluble protein was extracted using the organic phase of the TRIzol extraction

537   (n=6/mCHD, n=6/mHFD) from female amygdala. Ethanol (100%; 1:0.3 v/v to TRIzol) was added

538   to the organic phase and centrifuged at 2,000 x g for 5 min at 4 °C to pellet the DNA. Isopropanol

34

539   (1:1.5 v/v to TRIzol) was added to the supernatant, incubated at RT for 10 min, and later

540   centrifuged at 12,000 x g at 4 °C for 10 min to pellet the proteins. Protein pellet was washed 3x

541   with 0.3 M guanidine hydrochloride in 95 % ethanol (1:2 v/v to TRIzol) followed by a single wash

542   with 2 mL of 100 % ethanol. The pellet was air dried for 15 min and re-suspended in 200 μL of

543   1 % SDS. The protein concentrations were measured using Pierce ™ BCA Protein Assay Kit

544   (23225; Thermo Scientific) with a Albumin BSA Standards ranging from 2000 μg/mL to 0 μg/mL

545   using a Nanodrop Spectrophotometer cuvette system (ND-2000C; ThermoFisher Scientific).

546   **DNA Methyltransferase Activity**

547   Total DNMT activity was measured using EpiQuik™ DNA Methyltransferase

548   Activity/Inhibition Assay Kit (P-3001; Epigentek, Farmingdale, NY, USA) according to

549   manufacturer's instructions. Briefly, a dilution curve ranging from 5 μg to 60 μg was assayed using

550   pooled protein samples from P7 and P90 amygdala to determine the linear portion of the absorption

551   curve along with DNMT positive controls (50 μg/mL; provided by Epigentek) and blanks

552   (containing only assay buffer). According to the dilution curve, 50 μg of total protein was chosen

553   as the optimal range for both P7 and P90 amygdala samples. All samples, positive controls, and

554   blanks were run in duplicates according to manufacturer's instructions. Absorption was read using

555   a microplate reader (Versamax; Molecular Devices) at 450 nm within 2 min.

556   Total DNMT enzymatic activity was calculated using the following formula:

557

558     $$DNMT\ Activity\left(\frac{\frac{OD}{h}}{mg}\right) = \left(\frac{No\ inhibitor\ OD - Blank\ OD}{Protein\ Amount\ (ug) \times hr}\right) \times 1000$$

559

560   **Genomic DNA Extraction**

561   Genomic DNA (gDNA) was extracted using ZR-Duet™DNA/RNA MiniPrep (D7005;

562   Zymo Research, Irvine, CA, USA) according to manufacturing instructions (n=4/mCHD,

563   n=4/mHFD). The concentration of gDNA was quantified using the Pico Green dsDNA Assay

564   Kit (P11496; ThermoFisher Scientific).

565   **Global DNA Methylation**

566   Methylation of LINE-1 repeats have been implicated in several complex diseases and used

567   as representative of global levels of DNA methylation, as LINE-1 repeats make up approximately

568   18 % of the genome with copy number estimated at roughly half a million (Weisenberger et al.,

569   2005). Furthermore, LINE-1 methylation has a strong association with adiposity, dietary weight

570   gain, and body fat mass in humans (Carraro et al., 2016). As such, we used LINE-1 methylation

571   to measure changes in global methylation and the effects of mHFD exposure on 5mC levels.

572   Global % 5mC levels were assayed using a Global DNA Methylation LINE-1 Kit (55017; Active

573   Motif, Carlsbad, CA, USA) according to the manufacturer's instructions. A standard curve

574   (ranging from 0 ng to 100 ng) was prepared in triplicates using a mixture of methylated and non-

575   methylated DNA standards. A dilution curve (ranging from 0 ng to 500 ng) consisting of pooled

576   P7 and P90 gDNA samples were run in duplicate alongside the standard curve to determine the

577   linear portion of the absorbance readings at 450 nm. Based on the standard curve, 250 ng of gDNA

578   from P7 and 1 μg of gDNA from P90 were chosen for the assay. All absorption readings were

579   taken using a microplate reader (Versamax; Molecular Devices, San Jose, CA, USA) at 450 nm

580   with a reference wavelength of 655 nm within 5 min.

581   % 5mC levels were calculated by averaging the duplicates for the blanks and sample wells

582   and triplicates for the standards and subtracting the average blank OD at 450 nm from the average

583   standard ODs and sample ODs. % 5mC levels that were associated with each sample were

584 determined based on the total detectable CpG content. Using the standard curve ranging from 0 ng

585 to 100 ng (slope = 0.0297; R_2-value = 0.950), % 5mC methylation for each sample was

586 extrapolated using MyCurveFit Beta online curve fitting software (https://mycurvefit.com). As the

587 amount of DNA used was 60 ng and 80 ng for P7 and P90, respectively, the extrapolated % 5mC

588 values were further divided by the total amount of gDNA loaded and multiplied by 100.

589 **Reduced Representation Bisulfite Sequencing (RRBS)**

590 gDNA from P7 and P90 female amygdala used for the global methylation assay was also

591 used for RRBS analysis. Briefly, 100 ng of genomic DNA was used to construct libraries for RRBS

592 using the Ovation RRBS Methyl-Sequencing Kit (0553-32; NuGEN, Redwood City, CA, USA)

593 as per the manufacturer's instructions. The EpiTect Fast DNA Bisulfite Kit (59824; Qiagen) was

594 used for bisulfite conversion. Libraries were sequenced on a NextSeq 500 (Illumina, San Diego,

595 CA, USA) at the Princess Margaret Genomics Centre (University Health Network, Toronto) using

596 single end sequencing with a 75-base pair read length and multiplexed at 8–10 samples per

597 flowcell. Samples sequenced were as follows; for P7, mCHD: n=4 and mHFD: n=4 and for P90,

598 mCHD: n=6 and mHFD: n=4.

599 **DNA Methylation Analysis**

600 RRBS fastq files were processed as per our previous study. Files were trimmed to remove

601 low quality reads (q < 30) and adaptors, and later aligned to RGD Rnor_6.0 (Ashbrook et al.,

602 2018). The average reads per sample was $20.8X10_6$ with a mapping efficiency of 50-60 %.

603 Differentially methylated regions (DMRs) were identified using a dynamic sliding window

604 approach and annotated using the methylPipe (Song et al., 2013) and compEpiTools R packages

605 (Kishore et al., 2015). The bisulfite conversion rate was >99 % for all samples. Regions were

606   declared to be differentially methylated if the average methylation of at least 10 consecutive CpG

607   sites within a 1 Kb region was $\geq$ 5 % between mHFD and mCHD with FDR < 0.05.

Gene Set Enrichment Analysis

609   Set of differentially methylated genes identified by the DMR analysis were explored using

610   Gene Ontology Biological Processes (GO BP) (Ashburner et al., 2000; Blake et al., 2015) and

611   KEGG pathway enrichment analysis (Kanehisa et al., 2012) to examine functionally annotated

612   gene pathways and networks. Enrichment analysis was performed using gProfiler (Reimand et al.,

613   2016) with a FDR $\leq$ 0.05 cutoff for statistical significance.

614   Networks of GO terms were constructed and visualized using Enrichment Map on

615   Cytoscape 3.6.1 (Merico et al., 2010). Clusters were arranged and labeled using the yFiles

616   algorithm and WordCloud plugin on Cytoscape 3.6.1. GO analysis was also performed using

617   DAVID algorithm to compare to the results generated by gProfiler.

Statistical analysis

619   Statistical analysis was carried out using SPSS version 25 (IBM) and figures were

620   constricted using GraphPad Prism7. A Shapiro-Wilk test was used to test for normality for all

621   datasets. All data exhibited a normal distribution and thus parametric analyses were carried out.

622   Maternal and offspring bodyweights were analyzed using repeated measures analysis of variance

623   (ANOVA) Diet X Time. Dam's caloric intake, offspring relative transcript abundance of miRNA

624   and mRNA targets, DNMT enzymatic activity (OD/h/mg), and the global LINE-1 DNA

625   methylation (%), between mCHD and mHFD were analyzed using a two-tailed student t-test with

626   a 95 % confidence interval. Pearson correlation analysis was used to assess the relationship

627   between DNMT activity and % global DNA methylation levels. All relationships were considered

628   statistically significant at p $\leq$ 0.05.

629

636 **Competing Interests**

637 No financial or non-financial competing interests are associated with this manuscript.

638 **Author Contribution:**

639 S.A, S.W, and P.O.M contributed to the experimental design, conceptualization, and wrote the

640 paper.

641 S.A contributed to animal testing and sample collections for the P7 cohort, generated RRBS

642 libraries, and performed enrichment and network analysis.

643 S.W contributed to miRNA measurements and analysis, DNMT enzymatic assays and LINE-1

644 methylation assays.

645 W.C.D contributed to RRBS library construction of P90 samples, performed all bioinformatics

646 analysis of the sequencing data and generated the DMRs datasets.

647 S.A, S.W, W.C.D contributed to gDNA, RNA, and protein extractions from P7 and P90 samples.

648 S.W and C.W.M.L contributed to P7 and P90 qPCR measurements.

649 A.S contributed to P90 animal testing and sample collections.

650 **Data availability:**

651 The data sets generated and/or analyzed during the current study are available from the

652 corresponding author on request.
