- 8 Abstract
- 9 This article reviews thermodynamic relationships in the brain in an attempt to consolidate current
- 10 research in systems neuroscience. The present synthesis supports proposals that thermodynamic
- 11 information in the brain can be quantified to an appreciable degree of objectivity, that many
- 12 qualitative properties of information in systems of the brain can be inferred by observing changes in
- 13 thermodynamic quantities, and that many features of the brain's anatomy and architecture illustrate
- 14 relatively simple information-energy relationships. The brain may provide a unique window into the
- 15 relationship between energy and information.

16 Introduction

- 17 That information is physical has been suggested by evidence since the founding of classical
- 18 thermodynamics (J Gleick 2011; S Lloyd 2006). In recent years, Landauer's principle (CH Bennett
- 19 2003; R Landauer 1996), which relates information-theoretic entropy to thermodynamic information,
- 20 has been confirmed (JMR Parrondo et al. 2015), and the experimental demonstration of a form of
- 21 information-energy equivalence (A Alfonso-Faus 2013) has verified that Maxwell's demon cannot
- violate any known laws of thermodynamics (K Maruyama et al. 2009). The theoretical finding that
- 23 entropy is conserved as event horizon area is leading to the resolution of the black hole information
- paradox (P Davies 2010; C Moskowitz 2015), and there is a fundamental relationship between
- 25 information and the geometry of spacetime itself (R Bousso 2002; C Eling et al. 2006). Current
- 26 formulations of quantum theory are revealing properties of physical information (Č Brukner and A
- 27 Zeilinger 2003; S Lloyd 2006; V Vedral 2010; J Wheeler 1986), and information-interpretive
- attempts to show that gravity is quantized (JW Lee et al. 2013; L Smolin 2001) could even lead to the
- 29 unification of quantum mechanics and the theories of relativity. Although similar approaches are
- 30 increasingly influential in biology (JL England 2013; JC Flack 2014; ED Schneider and D Sagan
- 31 2005), "a formalization of the relationship between information and energy is currently lacking in
- 32 neuroscience" (G Collell and J Fauquet 2015). The purpose of this article is to explore a few different
- 33 sides of this relationship and, along the way, to suggest that many hypotheses and theories in
- 34 neuroscience can be unified by the physics of information.

35 Information bounds

36 *"How can the events in space and time which take place within the spatial boundary of a living*

organism be accounted for by physics and chemistry?" – (E Schrödinger 1944, from KJ Friston
2013)

As a fundamental physical entity (S Lloyd 2015), information is not fully understood, and there is currently a significant amount of disagreement over different definitions of information and entropy in the literature (A Ben-Naim 2015; B Poirier 2014). In thermodynamics, however, information can be defined as a negation of thermodynamic entropy (C Beck 2009):

 $I \equiv -S$

44 A bit of thermodynamic entropy represents the distinction between two alternative states in a

45 physical system (JV Stone 2015). As a result, the total thermodynamic entropy of a system is

46 proportional to the total number of distinguishable states contained in the system (JD Bekenstein

47 2001; JD Bekenstein 2007). Because thermodynamic entropy is potential information relative to an

48 observer (S Lloyd 2006), and an observer in a physical system is a component of the system itself,

49 the total thermodynamic entropy of a system includes the portion of entropy that is accessible to the

50 observer as relative thermodynamic information (G Collell and J Fauquet 2015; J Wheeler 1989):

51
$$I_{relative} = S_{total} - S_{relative}$$

52 Since entropy in any physical system is finite (S Lloyd 2006; C Rovelli 2015), the total

53 thermodynamic entropy of any system of the brain can be quantified by applying the traditional form

of the universal (JD Bekenstein 1981, 1984, 2001, 2004, 2007) information-entropy bound:

55
$$S_{sys} = \zeta \frac{AEk}{\hbar c}$$

56 where *A* is area, *E* is energy including matter, \hbar is the reduced Planck constant, *c* is the speed of light, *k* is 57 Boltzmann's constant, and ζ is a factor such that $0 \le \zeta \le 1$

58 Setting this factor to 1 in order to quantify the total thermodynamic entropy of a system at a certain

- 59 level of structure now allows us to quantify thermodynamic information by partitioning the factor
- 60 into a relative information component ($\zeta_I = 1 \zeta_S$) and a relative entropy component ($\zeta_S = 1 \zeta_I$),

61
$$I_{sys} = \zeta_I \frac{AEk}{\hbar c} = (1 - \zeta_S) \frac{AEk}{\hbar c}$$

62 Because a maximal level of energy corresponds to a maximal level of thermodynamic information,

63 and a minimal level of energy corresponds to a minimal level of thermodynamic information (TL

64 Duncan and JS Semura 2004), any transitions between energy levels occur as transitions between

65 informational extrema. So, in the event that information enters a system of the brain,

$$\Delta I_{sys} = \frac{\Delta E_{sys}}{kT} = \Delta \zeta_{I}$$

67 where *T* is temperature

68 and, in the event that information exits a system,

This is a provisional file, not the final typeset article

$$-\Delta I_{sys} = \frac{\Delta E_{surr}}{kT} = \Delta \zeta_S$$

70 Various forms of these relationships, including information-entropy bounds, have been applied in

neuroscience (G Collell and J Fauquet 2015; B Sengupta et al. 2013; B Sengupta and KJ Friston

- 72 2015; P Sterling and S Laughlin 2015). The contribution of this review is simply to show that these
- relationships can be united into a common theoretical framework.

74 Neurobiology

69

75 "... classical thermodynamics... is the only physical theory of universal content which I am

76 convinced, that within the framework of applicability of its basic concepts, will never be

77 *overthrown.* " – (A Einstein 1949, from JD Bekenstein 2001)

78 This section reviews thermodynamic relationships in systems neuroscience with a focus on

⁷⁹ information and energy. Beginning with neurons, moving to neural networks, and concluding at the

80 level of the brain as a whole, I discuss the energetics of processes such as learning and memory,

81 excitation and inhibition, and the production of noise in neurobiological systems.

82 The central role of energy in determining the activity of neurons exposes the close connection 83 between information and thermodynamics at the level of the cell. For instance, the process of depolarization, which occurs as a transition to E_{max} from a resting state E_{min} , clearly shows that 84 85 cellular information content is correlated with energy levels. In this respect, the resemblance between 86 ion concentration gradients in neurons and temperature gradients in thermodynamic demons (i.e., 87 agents that use information from their surroundings to decrease their thermodynamic entropy) is not a 88 coincidence – in order to acquire information, neurons must expend energy to establish proper 89 membrane potentials. Recall that Landauer's principle (JMR Parrondo et al. 2015; MB Plenio and V 90 Vitelli 2001) places a lower bound on the quantity of energy released into the surroundings with the 91 removal of information from a system. Thus, reestablishing membrane potentials after depolarization 92 - the neuronal equivalent of resetting a demon's memory - dissipates energy. Because Landauer's 93 principle applies to all levels of structure, and cells process large quantities of information, neurons 94 use energy efficiently despite operating at several orders of magnitude above the nominal limit. 95 Parameters including membrane area, spiking frequency, and axon length have all been optimized 96 over the course of evolution to allow neurons to process information efficiently (P Sterling and S

Laughlin 2015). Examining the energetics of information processing in neurons reinforces the notionthat, while it is often convenient to imagine the neuron to be a simple binary element, these cells are

99 intricate computational structures that process more than one bit of information.

100 Relationships between information and energy can also be seen at the level of neural 101 networks. Attractor networks naturally stabilize by seeking energy minima, and the relative positions 102 of basins of attraction define the geometry of an energy landscape (DJ Amit 1992). As a result, the 103 transition into an active attractor state occurs as a transition into an information-energy maximum. 104 These transitions correspond to the generation of informational entities such as memories, decisions, 105 and perceptual events (ET Rolls 2012). In this way, the energy basins of attractor networks may be 106 analogous to lower-level cellular and molecular energy gradients; a transition between any number of 107 distinguishable energy levels follows the passage of a finite quantity of information. Since processing 108 information requires the expenditure of energy, competitive network features also underscore the 109 need to minimize unnecessary information processing. Lateral inhibition at this level may optimize 110 thermodynamic efficiency by reducing metabolic expenses associated with networks responding less 111 robustly to entering signals. Another interesting thermodynamic property of networks concerns 112 macrostates: the functional states of large-scale neural networks rest emergently on the states of 113 neuronal assemblies (R Yuste 2015). As a result, new computational properties may arise with the

addition of new layers of network structure. Finally, the energetic cost of information has influenced
network connectivity by imposing selective pressures to save energy by minimizing path length
between network nodes (E Bullmore and O Sporns 2009).

Again, in accordance with Landauer's principle, the displacement of information from any 117 system releases energy into the surroundings (MB Plenio and V Vitelli 2001; TL Duncan and JS 118 119 Semura 2004). This principle can be understood by imagining an idealized memory device, such as 120 the brain of a thermodynamic demon. Since information is conserved (L Susskind and G Hrabovsky 121 2014), and clearing a memory erases information, the thermodynamic entropy of the surroundings 122 must increase when a demon refreshes its memory to update information. This fundamental 123 connection between information, entropy, and energy appears in many areas of the neurobiology of 124 learning. For example, adjusting a firing threshold in order to change the probability that a system 125 will respond to a conditioned stimulus (Y Choe 2015; T Takeuchi et al. 2014) optimizes engram 126 fitness by minimizing the quantity of energy needed for its activation (S Still et al. 2012). Recurrent 127 collateral connections further increase engram efficiency by enabling a minimal nodal stimulus to 128 elicit its full energetic activation (ET Rolls 2012). Experimental evidence also shows that restricting 129 synaptic energy supply impairs the formation of stable engrams (JJ Harris et al. 2012). Because the 130 formation and disassembly of engrams during learning and forgetting optimizes the growth and 131 pruning of networks in response to external conditions, the process of learning is itself a mechanism for minimizing entropy in the brain (KJ Friston 2003). 132

133 As another example of a multiscale process integrated across many levels by 134 thermodynamics, consider the active balance between excitation and inhibition in neurobiological 135 systems. Maintaining proper membrane potentials and adequate concentrations of signaling 136 molecules requires the expenditure of energy, so it is advantageous for systems of the brain to 137 minimize the processing of unnecessary information - to "send only what is needed" (P Sterling and 138 S Laughlin 2015). Balancing excitation and inhibition is therefore a crucial mechanism for saving 139 energy. Theoretical evidence that this balancing maximizes the thermodynamic efficiency of 140 processing Shannon information (B Sengupta et al. 2013) is consistent with experimental findings in 141 several areas of research on inhibition. For instance, constant inhibitory modulation is needed to 142 stabilize internal states, and hyperexcitation (e.g., in epilepsy, intoxication syndromes, or trauma) can 143 decrease relative information by reducing levels of consciousness (B Haider et al. 2006; K Lehmann 144 et al. 2012). Likewise, selective attention is mediated by the activation of inhibitory interneurons (G 145 Houghton and SP Tipper 1996), and sensory inhibition appears to sharpen internal perceptual states 146 (JS Isaacson and M Scanziani 2011). The need to balance excitation and inhibition at all levels of 147 structure highlights the energetic cost of information.

148 A final example worth discussing is the relationship between thermodynamics and the 149 production of noise in neurobiological systems. Noise is present in every system of the brain, and 150 influences all aspects of the organ's function (AA Faisal et al. 2008; ET Rolls and G Deco 2010; A 151 Destexhe and M Rudolph-Lilith 2012). Even in the absence of any potential forms of classical 152 stochastic resonance, the noise-driven exploration of different states may optimize thermodynamic efficiency by allowing a system to randomly sample different accessible configurations. Theoretical 153 154 arguments suggest indeed that noise enables neural networks to respond more quickly to detected signals (ET Rolls 2012), and empirical evidence implicates noise as a beneficial means of optimizing 155 156 the performance of diverse neurobiological processes (MD McDonnell and LM Ward 2011). For 157 example, noise in the form of neuronal DNA breaking (JU Guo et al. 2011; K Herrup et al. 2013; P 158 Tognini et al. 2015) could enhance plasticity, since any stochastically optimized configuration would 159 be more likely to survive over time as, in this case, a strengthened connection in a modifiable 160 network. Because noise is a form of relative entropy, optimizing the signal-to-noise ratio in any 161 neurobiological system promotes the efficient use of energy.

162 At the level of the brain as a whole, the connection between information and thermodynamics

- 163 is readily apparent in the organ's functional reliance on energy (PJ Magistretti and I Allaman 2015),
- 164 its seemingly disproportionate consumption of oxygen and energy substrates (e.g., ATP, glucose,
- 165 ketones, etc.) (S Herculano-Houzel 2011; ME Raichle and DA Gusnard 2002), its vulnerability to
- 166 hypoxic-ischemic damage (JP Dreier et al. 2013; PL Lutz et al. 2003) and in the reduction of
- 167 consciousness often conferred by the onset of energy restrictions (RG Shulman et al. 2009; J Stender
- 168 et al. 2016). All fMRI, PET, and EEG interpretation rests on the foundational assumption that
- 169 changes in the information content of neurobiological systems can be inferred by observing energy
- 170 changes (D Attwell and C Iadecola 2002; G Collell and J Fauquet 2015), and it is well known that the
- information processing capacities of neurobiological systems are limited by energy supply (C
 Howarth et al. 2012). Overall, these relationships are consistent with the form of information-energy
- Howardi et al. 2012). Overall, these relationships are consistent with the form of information-energy
- equivalence predicted by Landauer's principle and information-entropy bounds. The living brain
- appears to maintain a state of thermodynamic optimization.

175 **Consciousness and free will**

176 "... science appears completely to lose from sight the large and general questions; but all the more

- 177 splendid is the success when, groping in the thicket of special questions, we suddenly find a small
- 178 opening that allows a hitherto undreamt of outlook on the whole." (L Boltzmann 1886, from HC
- 179 Von Baeyer 1999)

180 Although neuroscience has yet to explain consciousness or free will at any satisfactory level of detail,

- 181 relationships between information and energy seem to be recognizable even at this level of analysis.
- 182 This section reviews attempts to conceptualize major properties of consciousness (unity, continuity,
- 183 complexity, and self-awareness) as features of information processing in the brain, and concludes184 with a discussion of free will.
- 185 At any given moment, awareness is experienced as a unified whole. Physical information is 186 the substrate of consciousness (A Annila 2016), and the law of conservation of information requires 187 any minimal unit of information to be transferred into a thermodynamic system as a temporally 188 unitary quantity. As a result, it is possible that the passage of perceptual time itself occurs secondarily 189 to the transfer of information, and that the information present in any integrated system of the brain at 190 any observed time is necessarily cohesive and temporally unified. In this framework, the passage of 191 time would vary in proportion to a system's rate of energy dissipation. Although it is possible that 192 physical systems in general exchange information in temporally unitary quantities, it is likely that 193 many of the familiar features of the perceptual unity of consciousness require the structure and 194 activity of neural networks in the brain. The biological basis of this unity may be the active temporal 195 consolidation of observed events by integrated higher-order networks (S Dehaene and JP Changeux 196 2011; SA Greenfield and TFT Collins 2005; A Revonsuo 1999; F Varela et al. 2001). An 197 informational structure generated by the claustrum has been speculated to contribute to this 198 experiential unity (FC Crick and C Koch 2005, MZ Koubeissi et al. 2014), but it has also been 199 reported that complete unilateral resection of the system performed in patients with neoplastic lesions 200 of the region produces no externally observable changes in subjective awareness (H Duffau et al.
- 201 2007). Overall, it appears unlikely that the presence of information in any isolated or
- 202 compartmentalized network of the brain is responsible for generating the unified nature of conscious
 203 experience.

While perceptual time is likely the product of a collection of related informational processes rather than a single, globalized function mediated by any one specific system of the brain, some of the perceptual continuity of consciousness may result from the effectively continuous flow of thermodynamic information into and out of integrated systems of the brain. In this framework, the quantum (M Prokopenko et al. 2014) of perceptual time would be the minimal acquisition of 209 information, and the entrance of information into neurobiological systems would occur alongside the 210 entrance of energy. This relationship is implicit in the simple observation that the transition of a 211 large-scale attractor network is progressively less discrete and smoother in time than the activation of 212 a small-scale engram, the propagation of a cellular potential, the docking of a vesicle, the release of an ion, and so forth. Likewise, electroencephalography shows that the summation of a large number 213 214 of discrete cellular potentials can accumulate into an effectively continuous wave as a network field 215 potential (PL Nunez and R Srinivasan 2006), disruptions of which are often correlated with decreases 216 in levels of consciousness (H Blumenfeld and J Taylor 2003). It is also well known that higher 217 frequency network oscillations tend to indicate states of wakefulness and active awareness, while 218 lower frequency oscillations tend to be associated with internal states of lesser passage of perceptual 219 time, such as dreamless sleep or unconsciousness. The possibility that the experiential arrow of time 220 and the thermodynamic arrow of time share a common origin in the flow of information is supported 221 both by general models of time in neuroscience and the physical interpretation of time as an entropy 222 gradient (L Mlodinow and TA Brun 2014; OC Stoica 2008).

223 The subjective complexity of consciousness may show that extensive network integration is 224 needed for maximizing the mutual thermodynamic information and internal energy content of 225 systems of the brain (JS Torday and WB Miller Jr 2016). An exemplary structure enabling such 226 experience, likely one of many that together account for the subjective complexity of consciousness, is the thalamocortical complex (Y Hannawi et al. 2015; RS Calabrò et al. 2015). The functional 227 228 architecture of such a network may show that, at any given moment in the internal model of a living 229 brain, a wide range of integrated systems are sharing mutual sources of thermodynamic information. 230 This pattern of structure may reveal that the perceptual depth and complexity of conscious experience 231 is a direct product of recognizable features of the physical brain. However, it also seems that 232 extensive local cortical processing of information is necessary for producing a refined and coherent 233 sensorium within a system, and that both the thalamocortical complex and the brain stem are 234 involved in generating the subjective complexity of consciousness (GM Edelman et al. 2011; LM 235 Ward 2011). The dynamics of attractor networks at higher levels of network structure may show that 236 quantities of complex internal information can be observed as changes in cortical energy landscapes 237 (ET Rolls 2012), with a transition between attractor states following the transfer of information. The 238 degree of subjective complexity of information enclosed by such a transition would be proportional 239 to the degree of structural integration of underlying networks.

240 Self-awareness likely arose as a survival necessity rather than as an accident of evolution (F 241 Fabbro et al. 2015), and rudimentary forms of self-awareness likely began to appear early in the 242 course of brain evolution as various forms of perceptual self-environment separation. As a simple 243 example, consider the tickle response (DJ Linden 2007), which requires the ability to differentiate 244 self-produced tactile sensations from those produced by external systems. The early need to 245 distinguish between self-produced tactile states and those produced by more threatening non-self 246 sources may be reflected by the observation that this recognition process is mediated to a great extent 247 by the cerebellum (SJ Blakemore et al. 2000). While it is possible that other similar developments began occurring very early on, the evolutionary acquisition of the refined syntactical and conceptual 248 249 self present in the modern brain likely required the merging of pre-existing self networks with 250 higher-level cortical systems. The eventual integration of language and self-awareness would have 251 been advantageous for coordinating social groups (MS Graziano 2013), since experiencing self-252 referential thought as inner speech facilitates verbal communication. Likewise, the coupling of self-253 awareness to internal sensory, cognitive, and motor states (T Metzinger 2004; G Northoff et al. 2006) 254 may be advantageous for maximizing information between systems within an individual brain. 255 Neuropsychological conditions involving different forms of agnosia, neglect, and self-awareness 256 deficits do show that a reduced awareness of self-ownership of motor skills, body parts, or perceptual 257 states can result in significant disability (F Fabbro et al. 2015; S Chokron et al. 2016; MD Orfei et al.

2007; M Overgaard 2011; A Parton et al. 2004; M Tsakiris 2010; A Morin 2006; GP Prigatano
2009). Since experiencing self-awareness optimizes levels of mutual information between the
external world and the brain's internal model (MA Apps and M Tsakiris 2014), and this activity
decreases thermodynamic entropy (JS Torday and WB Miller Jr 2016), self-awareness may be a
mechanism for optimizing the brain's consumption of energy.

263 Thermodynamic information is also interesting to consider in the context of free will. The 264 brain is predictable within reason, and the performance of an action can be predicted before a 265 decision is reported to have been made (P Haggard 2008). Entities such as ideas, feelings, and beliefs 266 seem to exist as effectively deterministic evaluations of information processed in the brain. Whether 267 or not the flow of information is subject to the brain's volitional alteration, neuroscience also shows that information can be internally real to a system of the brain, even if this information is inconsistent 268 269 with an external reality. That the brain can generate an externally inconsistent internal reality is 270 demonstrated by phenomena such as confabulation, agnosia, blindsight, neglect, commissurotomy 271 and hemispherectomy effects, placebo and nocebo effects, reality monitoring deficits, hallucinations, 272 prediction errors, the suspension of disbelief during dreaming, the function of communication in 273 minimizing divergence between internal realities, the quality of many kinds of realistic drug-induced 274 experiences, and the effects of many neuropsychological conditions. The apparent fact that subjective 275 reality is an active construction of the physical brain has even led to the proposal of model-dependent 276 realism (SW Hawking and L Mlodinow 2011) as a philosophical paradigm in the search for a unified 277 theory of physics. In any case, it is likely that beliefs, including those in free will, exist as 278 information, and that their internal reality is a restatement of its frequently observer-dependent 279 nature.

280 Empirical outlook

Before concluding, it is worth reviewing a few notable experiments in greater detail. While 281 282 considerable advances have been made in discovering how neurobiological systems operate 283 according to principles of thermodynamic efficiency (S Laughlin and P Sterling 2015), relationships 284 between information and energy in the brain are only beginning to be understood. The following 285 studies are examples of elegant and insightful experiments that should inspire future research. 286 Several recent brain imaging studies support the proposal (A Annila 2016) that 287 thermodynamics is able to explain a number of mysteries involving consciousness. For example, J 288 Stender et al. 2016 used PET to measure global resting state energy consumption in 131 brain injury 289 patients with impairments of consciousness as defined by the revised Coma Recovery Scale (CRS-290 R). The preservation of consciousness was found to require a minimal global metabolic rate of $\approx 40\%$ 291 of the average rate of controls; global energy consumption above this level was reported to predict 292 the presence or recovery of consciousness with over 90% sensitivity. These results must be replicated 293 and studied in closer detail before their specific theoretical implications are clear, but it is now 294 established that levels of consciousness are correlated with energetic metrics of brain activity. To 295 what extent there exists a well-defined "minimal energetic requirement for the presence of conscious 296 awareness" (J Stender et al. 2016) remains an open question. However, the empirical confirmation of 297 a connection between consciousness and thermodynamics introduces the possibility of developing 298 new experimental methods in consciousness research. 299 Neurobiological systems, and biological systems in general (HC Von Baeyer 1999; ED

Schneider and D Sagan 2005), can be considered thermodynamic demons in the sense that they are agents using information to decrease their thermodynamic entropy. Landauer's principle requires that, in order not to violate any known laws of thermodynamics, such agents dissipate heat when erasing information from their memory storage devices. In an experimental test of this principle, reviewed along with similar experiments in JMR Parrondo et al. 2015, A Bérut et al. 2012 studied 305 heat dissipation in a simple memory device created by placing a glass bead in an optical double-well 306 potential. Intuitively, this memory stored a bit of information by retaining the bead on one side of the potential rather than on the alternative. By manipulating the height of the optical barrier between 307 wells, researchers moved the bead to one side of the memory without determining its previous 308 309 location in the potential. This process was therefore logically irreversible, requiring the erasure of 310 prior information from the memory device. Landauer's principle predicts that, since information is 311 conserved, the entropy of the memory's surroundings must increase when this occurs. A Bérut et al. 312 2012 have verified that energy is emitted when a memory is cleared. As noted by the authors, "this 313 limit is independent of the actual device, circuit or material used to implement the irreversible 314 operation." It would be interesting to study the erasure principle in the context of neuroscience. 315 Experimental applications of information theory in cell biology have already led to the 316 discovery of general principles of brain organization related to thermodynamics (S Laughlin and P 317 Sterling 2015). In one particularly interesting study, JE Niven et al. 2007 measured the energetic 318 efficiency of information coding in retinal neurons. Intracellular recordings of membrane potential 319 and input resistance were used to calculate rates of ATP consumption in response to different 320 background light intensities. These rates of energy consumption were then compared with rates of 321 Shannon information transmission in order to determine metabolic performance. It was found that

322 metabolic demands increase nonlinearly with respect to increases in information processing rate:

thermodynamics appears to impose a "law of diminishing returns" on systems of the brain. The authors interpret these results as evidence that nature has selected for neurons that minimize

325 unnecessary information processing. Studying how thermodynamics has influenced cellular

parameters over the course of evolution is likely to raise many new empirically addressable

327 questions.

328 Conclusion

329 This article has reviewed information-energy relationships in the hope that they may eventually

provide a general framework for uniting theory and experiment in neuroscience. The physical nature

of information and its status as a finite, measurable resource are emphasized to connect neurobiology

and thermodynamics. As a scientific paradigm, the information movement currently underway in

333 physics promises profound advances in our understanding of the relationship between energy,

information, and the physical brain.

335 Conflict of Interest

The author confirms that this research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

338 Acknowledgements

339 I am grateful to Baroness Susan Greenfield, Dr. Francesco Fermani, Dr. Karl Friston, Dr. Biswa

340 Sengupta, Dr. Roy Frieden, Dr. Bernard Baars, Dr. Brett Clementz, Dr. Cristi Stoica, Dr. Satoru

341 Suzuki, Dr. Paul King, Guillem Collell Talleda, Dr. Jordi Fauquet, and others who have helped me

342 improve these ideas. I am also grateful to Dr. Shanta Dhar and her team for introducing me to

343 academic research, to Jim Reid for introducing me to biology, to Alex Tisch for introducing me to 344 physics, and to those affiliated with the Department of Neurosurgery at the University of Virginia

345 Medical Center for introducing me to neuroscience.
