Abstract

22 Mate recognition in animals evolves during niche adaptation and involves habitat and

23 social olfactory signals. *Drosophila melanogaster* is attracted to fermenting fruit for

24 feeding and egg-laying. We show that, in addition, female flies release a pheromone (*Z*)-

25 4-undecenal (*Z*4-11Al), that elicits flight attraction in both sexes. The biosynthetic

26 precursor of *Z*4-11Al is the cuticular hydrocarbon (*Z,Z*)-7,11-heptacosadiene (7,11-HD),

27 which is known to afford reproductive isolation between the sibling species *D.*

28 *melanogaster* and *D. simulans*. A pair of alternatively spliced receptors, Or69aB and

29 Or69aA, is tuned to *Z*4-11Al and to food olfactory cues, respectively. These receptors are

30 co-expressed in the same olfactory sensory neurons, and feed into a neural circuit
31 mediating species-specific, long-range communication: the close relative *D. simulans*,
32 which shares food resources and co-occurs with *D. melanogaster*, does not respond. That
33 Or69aA and Or69aB have adopted dual olfactory traits highlights the interplay of habitat
34 and social signals in mate finding. These olfactory receptor genes afford a collaboration
35 between natural and sexual selection, which has the potential to drive phylogenetic
36 divergence.

Keywords

38 pheromone, kairomone, olfaction, reproductive isolation

Significance Statement

40 Volatile insect sex pheromones carry a message over a distance, they are perceived by
41 dedicated olfactory receptors, and elicit a sequence of innate behaviours. Pheromones
42 mediate specific mate recognition, but are embedded in and perceived together with
43 environmental olfactory cues. We have identified the first long-range, species-specific
44 pheromone in *Drosophila melanogaster*. A pair of spliced olfactory receptors, feeding into
45 the same neural circuit, has developed a dual affinity to this pheromone and kairomones,
46 encoding adult and larval food. Blends of this pheromone and kairomone specifically
47 attract *D. melanogaster*, but not the close relative *D. simulans*. This becomes an
48 excellent paradigm to study the interaction of social signals and habitat olfactory cues in
49 premating reproductive isolation and phylogenetic divergence.

50 \body

Introduction

52 Volatile insect pheromones transmit species-specific messages and elicit long-range flight
53 attraction. Premating communication with pheromones facilitates and accelerates mate-
54 finding, and reduces predation risk and energy expenditure, which is particularly adaptive
55 in short-lived insects (1,2).

56 Sexual communication subserves mate-finding and ultimately reproduction. Female
57 insects search for larval food and oviposition sites soon after mating, and both sexes

58   forage to offset the nutritional cost of reproduction. The search for mates and food is
59   accordingly interconnected, and so is the response to sex and habitat olfactory signals.
60   The sensory drive hypothesis predicts that mate recognition in animals evolves during
61   niche adaptation and that premating sexual communication involves olfactory
62   specialization to both social signals and habitat cues (3,4).

63   Pheromones are released into an atmosphere that is filled with environmental, habitat-
64   related olfactory cues, some of which signal mating sites and food sources. The response
65   to sex pheromones and food or habitat odourants (kairomones) is under sexual and
66   natural selection, respectively. Pheromones and kairomones are always perceived as an
67   ensemble in a natural context and this leads to an interaction of sexual and natural
68   selection during adaptive divergence of sexual signaling, which is thought to facilitate
69   premating reproductive isolation (3-7).

70   Olfactory sexual communication is studied at cellular and molecular resolution in the fruit
71   fly *Drosophila melanogaster*, but volatile pheromones encoding species-specific, long-
72   range mate recognition have not yet been found. *Drosophila* is attracted to yeast and
73   fruit odorants for feeding, mating and oviposition (8-10) and the interconnection between
74   perception of pheromones and food semiochemicals is a current research theme (11, 12).
75   For example, the male-produced sex pheromone cVA and food stimuli are integrated to
76   coordinate feeding, courtship behavior and oviposition site selection (13-16). Perception
77   of cVA is a current and outstanding paradigm for studying the molecular and neuronal
78   logic of innate, olfactory-mediated reproductive behavior (15, 17, 18). cVA and other
79   known olfactory pheromones are active during courtship, and since they are all shared
80   with other *Drosophila* species, they cannot account for species-specific communication
81   (19, 20, 21).

82   *D. melanogaster* and *D. simulans* are sibling species with no gene flow between them
83   (22). Interspecific matings of *D. melanogaster* with *D. simulans*, or other closely related
84   species are inhibited by the female-produced cuticular hydrocarbon (*Z,Z*)-7,11-
85   heptacosadiene (7,11-HD), which is perceived through gustatory receptors at close range
86   (23-25). 7,11-HD or other non-volatile cuticular hydrocarbons convey species-specificity,
87   but they are not volatile and cannot account for long-range communication and flight
88   attraction. This raises the question whether *Drosophila* uses, in addition, volatile
89   pheromone signals that mediate specific mate recognition at a distance.

90   We have identified the first long-range, species-specific pheromone in *D. melanogaster*. A
91   pair of spliced olfactory receptors, feeding into the same neural circuit, has developed a
92   dual affinity to this pheromone and to environmental semiochemicals, encoding adult and
93   larval food. A blend of this pheromone and a food odourant specifically attracts *D.
94   melanogaster*, but not the close relative *D. simulans*. This becomes an excellent paradigm
95   for studying the interaction of social signals and habitat olfactory cues in premating
96   reproductive isolation and phylogenetic divergence.

97 ## Results

98 ### *Drosophila melanogaster* **females produce a suite of volatile aldehydes.**

99 A focus in *Drosophila* pheromone research has been on cuticular hydrocarbons, which are
100 active during close-range courtship. Our scope was to investigate volatile compounds
101 encoding long-range communication. We therefore collected volatile compounds released
102 by *D. melanogaster* flies in a glass aeration apparatus and found 16 aliphatic aldehydes,
103 according to chemical analysis by gas chromatography-mass spectrometry (GC-MS).
104 Males and females shared saturated aldehydes with a carbon chain length of C7 to C18,
105 but mono-unsaturated aldehydes were released by females only (Fig. 1*A*; Table 1). The
106 most abundant compound was identified as (*Z*)-4-undecenal (*Z*4-11Al) and synthesized.

107 GC-MS analysis showed that *Z*4-11Al was present also in cuticular extracts of females,
108 although in lower amounts (0.27 ± 0.12 ng/female, *n* = 5) than in headspace collections
109 (3.0 ± 0.81 ng/female, *n* = 10; *P*<0.01 Mann-Whitney test). Cuticular profiles of
110 *Drosophila* flies have been investigated, but *Z*4-11Al or other aldehydes have not been
111 reported (19, 26, 27).

112 The sister species *D*. *simulans* did not release *Z*4-11Al, nor other monounsaturated
113 aldehydes (Fig. 1*A*). Unlike *D*. *melanogaster*, *D. simulans* does not produce (*Z,Z*)-7,11-
114 heptacosadiene (7,11-HD) (23). This led us to hypothesize that the production of mono-
115 unsaturated aldehydes with a double bond in position 4 was linked to oxidation of di-
116 unsaturated cuticular hydrocarbons. Oxidation of 7,11-HD is expected to generate two
117 saturated aldehydes, heptanal and hexadecanal, and two unsaturated aldehydes, *Z*4-11Al
118 and (*Z*)-4-eicosenal (Fig. 1*B*). This was experimentally verified by applying 100 ng
119 synthetic 7,11-HD to a glass vial. After 60 min, 1.92 ± 0.42 ng *Z*4-11Al were retrieved (n
120 = 3). Based on the cuticular hydrocarbon profile of *D. melanogaster* (24), 26 aldehydes
121 are expected to be formed by oxidation, 16 of which were found in our headspace
122 analysis (Table 1), others may have been below detection level.

123 Next, single sensillum electrophysiological recordings (SSR) from all basiconic, trichoid,
124 coeloconic, and intermediate olfactory sensilla in *D. melanogaster* (Fig. 1*C*) and GC-
125 coupled SSR recordings (GC-SSR) from ab9 sensilla (Fig. 1*D*) showed that *Z*4-11Al
126 strongly activates ab9A olfactory sensory neurons (OSNs). A weaker response from ab4A
127 neurons to *Z*4-11Al probably reflects the sensitivity of Or7a (expressed in ab4A) to
128 aldehydes, such as the leaf volatile (*E*)-2-hexenal or bombykal, a lepidopteran
129 pheromone compound (28-30).

The olfactory receptor Or69aB responds to *Z*4-11Al.

ab9A OSNs express the olfactory receptor (Or) Or69a (31). We therefore screened ab9A OSNs with known ligands of Or69a (30) and *Z*4-11Al. In the *D. melanogaster* strains Canton-S and Zimbabwe, the monoterpene (*R*)-carvone elicited the strongest response from ab9A, although the response to *Z*4-11Al was not significantly different. In *D. simulans*, Z4-11Al elicited a significantly lower response than (*R*)-carvone (Fig. 2*A*).

The Or69a gene encodes two proteins, Or69aA and Or69aB, as a result of alternative splicing (Fig. 2*D*), which occurred prior to the split of the *D. obscura* and *D. melanogaster* groups (32, 33). Heterologous co-expression of both Or69a splice variants in ab3A (*Δhalo*) empty neurons (34) produced a response similar to native ab9A OSNs; whereas individual expression revealed distinct response profiles for Or69aA and Or69aB (Fig. 2 *A* and *B*). Or69aB responds best to both isomers of carvone, followed by *Z*4-11Al.

Carvone and *Z*4-11Al, which seem unalike at first glance, share a structural motif, a carbonyl functional group with an equidistant double bond in position 4 (Fig. 2 *B* and *C*). Different ligands, upon binding to the same Or, are thought to adopt a complementary bioactive conformation. The strain energy required for any compound to assume a steric conformation that aligns with an active ligand should typically not exceed 5 kcal/mol (35). Conformational analysis showed that *Z*4-11Al aligns with (*R*)-carvone, which elicited the strongest Or69aB response, at a strain energy cost of only 1.5 kcal/mol. Or69aA, on the other hand, is tuned to terpenoid alcohols and responded significantly less to *Z*4-11Al. The most active ligands (*S*)-terpineol, (*S*)- and (*R*)-linalool, which again share the functional group and a double bond in position 4, align at 3.0 kcal/mol (Fig. 2 *B* and *C*). Conformational analysis confirms that the most active ligands for Or69aA and Or69aB, respectively, are structurally related.

Z4-11Al elicits upwind flight attraction in *D. melanogaster*, but not in *D. simulans*.

*Z*4-11Al elicited upwind flight and landing at the source, in cosmopolitan Dalby and Canton-S strain *D. melanogaster* males and females. In contrast, males of the Zimbabwe strain and *D. simulans* were not attracted (Fig. 3 *A* and *B*). This shows that *Z*4-11Al, in addition to its precursor 7,11-HD (Fig. 1) participates in sexual isolation between *D. melanogaster* and its sister species *D. simulans* (23), and between cosmopolitan and African *D. melanogaster* strains (36-38).

Moreover, admixture of *Z*4-11Al eliminated *D. simulans* attraction to the yeast volatile (*R*)-linalool (39) (Fig. 3*A*). *D. melanogaster* and its sister species *D. simulans* co-occur in the same habitat and use partially overlapping food resources. The very rarely occurring hybrid matings are sterile; the antagonistic interaction between pheromone and food stimulus is therefore adaptive and substantiates a contributing role of Or69a in

167   reproductive isolation. A tentative explanation for the significantly reduced attraction
168   response of *D. melanogaster* females to the blend of *Z*4-11Al and linalool, compared to
169   males (Fig. 3*A*) is that females would avoid food resources and rendezvous sites
170   overcrowded with other females.

171   The response magnitude of wild-type flies to Z4-11Al released at a rate of 10 ng/min was
172   similar to the upwind flight response to vinegar headspace, when the main compound
173   acetic acid was released at a 170-fold amount (Fig. 3*A*; 36). This illustrates the high
174   responsiveness and sensitivity of *D. melanogaster* males and females to Z4-11Al.

175   Finally, we used tetanus toxin mutants to verify that Or69a encodes *Z*4-11Al. Upwind
176   flight attraction to *Z*4-11Al or linalool was significantly reduced when Or69a OSNs were
177   disrupted (Fig. 3*B*). In summary, *Z*4-11Al is a powerful attractant that enables specific
178   mate recognition at a distance. Its heterospecific role was conserved even in blends with
179   the food attractant linalool.

Conclusions

181   *Z*4-11Al is the first species-specific, long-range sex pheromone of *D. melanogaster*. It is
182   produced by females and perceived by Or69aB in both sexes. The precursor of *Z*4-11Al is
183   the cuticular hydrocarbon 7,11-HD, which mediates isolation between *D. melanogaster*
184   and its sister species *D. simulans* during courtship (23-25).

185   In addition to pheromone, Or69aB and its twin receptor Or69aA bind kairomonal
186   terpenoids, such as linalool or terpineol, which are found in both fruit and yeast
187   headspace. Citrus peel, a preferred oviposition substrate (8), and baker's yeast which
188   grows on ripe fruit and elicits fly attraction and oviposition (9) are sources of all main
189   ligands of Or69aA and Or69aB (39, 41).

190   Combined pheromone and food odour tuning in the two Or69a splice variants underscores
191   the tie between sexual and natural selection during the evolution of specific mate
192   communication (3, 4). Flies releasing pheromone tint pervading habitat and food
193   odorants and thus shape and foreground a communication channel that facilitates mate
194   finding. This is particularly adaptive in *Drosophila* when mating sites, fruit and berries,
195   are abundant and widely spread.

196   A twin receptor, emerging from the Or69a splice event (32,33), facilitated adaptive
197   changes in ligand tuning, without compromising the established functional role of the
198   Or69a channel. Functional divergence has apparently been biased towards structurally
199   related ligands (Fig. 2 *B* and *C*; 30) and ecologically relevant odorant signals. This is

200 expected; conservative diversification of the splice variants is constrained to a behavioral
201 theme, since both Ors feed into one OSN.

202 Olfactory representations of other *Drosophila* Ors involved in food and pheromone
203 perception project through separate channels to the LH, where third-order neurons
204 partially overlap and integrate (15). In stark contrast, Or69a is the first olfactory gene
205 known to encode dual olfactory traits. Or69aA and Or69aB co-express in the same ab9A
206 OSNs (31) and thus achieve a coordination of mating and food stimuli already in first
207 order neurons, at the antennal periphery. This makes Or69a a target for selection during
208 phylogenetic divergence. The tuning range of Ors evolves more rapidly than hardwired
209 neural circuits in higher brain centres (42) and selection pressure is further relaxed
210 following a splice event. Differential tuning of Or69a in closely related cosmopolitan and
211 African strains of *D. melanogaster* (Fig. 2 *A*) corroborates this idea.

212 Tuning changes in the two splice forms of Or69a are restricted with respect to the
213 behavioral and ecological role of their ligands, since they both feed into a neural circuit
214 mediating sexual and habitat attraction. The two splice forms provide, on the other hand,
215 degrees of freedom during adaptive divergence, since they allow fly populations to adopt
216 new kairomone or pheromone signals; alteration of either one produces a new
217 communication channel. Reproductive isolation may arise as a byproduct (43-45) and the
218 Or69a gene therefore has the potential to drive speciation (46, 47). Species in the *D.*
219 *melanogaster* and *D. obscura* groups provide a rich substrate for studying Or ligand
220 evolution and its consequences on disruptive selection on ecological interactions and
221 mate choice.

Methods

Insects

224 Canton-S, Zimbabwe (S-29; Bloomington #60741) and Dalby-HL (Dalby, Sweden) (48)
225 strains of *D. melanogaster* were used as wild type flies for behavioral experiments.
226 Canton-S was used for comparison with knockouts of the same background. Further tests
227 were done with the sister species *D. simulans*.

228 We used the Or69a-Gal4/UAS TeTx, tetanus toxin knockout line to verify the role of
229 Or69a in flight attraction to *Z*4-11Al. Canton-S/UAS TeTx (Bloomington #28838 and
230 28997) and Canton-S/Or69a-Gal4 (Bloomington #10000) were used as parental controls.

231 Flies were reared on a standard sugar-yeast-cornmeal diet at room temperature (19 to
232 22°C) under a 16:8-h L:D photoperiod. Newly emerged flies were anesthetized under CO_2
233 and sexed under a dissecting microscope. Virgin flies were identified by the presence of

234 meconium, and were kept together with flies of the same sex. Flies were kept in 30-ml
235 Plexiglas vials with fresh food. Experiments were done with 3- to 5-d-old flies.

Chemicals

237 (*Z*)-4-undecenal (*Z*4-11Al) and (*E*)-4-undecenal (*E*4-11Al) were synthesized. A short
238 description follows below, for a complete account of the chemical synthesis, see
239 Supplemental Information.

240 (*Z*)-4-Undecenoic acid was synthesized via a modified version of Wube et al. (49) in 80%
241 stereoisomeric purity. Esterification under acidic conditions with sulfuric acid in methanol
242 resulted in 80% *Z*-isomer and a 93% yield over two steps. Stereoisomeric purity was
243 controlled with NMR and GC-FID by comparing analysis for acid and ester, the
244 appearance of a small quartet, in the NMR spectra, at 1.96 indicates the presence of *E*-
245 isomer. Gas chromatographic separation on a polar Varian factorFOUR vf-23ms of *Z*- and
246 *E*-ester proved that the stereochemistry was not affected by the acidic conditions during
247 esterification. Methyl (*Z*)-4-undecenoate was purified on regular silica gel and on silver
248 nitrate impregnated silica gel to obtain a stereoisomeric purity of 98.6%. Methyl (*Z*)-4-
249 undecenoate was reduced to (*Z*)-4-undecenol with lithium aluminum hydride in
250 diethylether and oxidized to *Z*4-11Al with Dess-Martin periodinane in dichloromethane.

251 A modified version of Virolleaud's (50) metathesis was used to produce (*E*)-4-undecenoic
252 acid in a 56% yield (87.5% of the *E*-isomer). (*E*)-4-undecenoic acid was esterified under
253 the same conditions as the (*Z*)-acid, without isomerisation of the double bond (according
254 to GC-FID and ^{1}H-NMR). The methyl-(*E*)-4-undecenoate was reduced to the alcohol with
255 lithium aluminum hydride in diethylether and purified on silver nitrate impregnated silica
256 gel to obtain a purity of 99.8% of the (*E*)-isomer, which was oxidized with Dess-Martin
257 periodinane in dichloromethane to obtain *E*4-11Al.

258 Commercially available compounds were: (*R*)-carvone (97% chemical purity, CAS #6485-
259 40-1, Firmenich), (*S*)-carvone (98%, CAS #2244-16-8, Firmenich), (*S*)-terpineol (97%,
260 CAS #10482-56-1, Aldrich), (*S*)-linalool (97%, CAS #126–91–0, Firmenich), (*R*)-linalool
261 (97%, CAS #126-90-9, Firmenich), citronellol (99%, CAS #106-22-9, Aldrich), geraniol
262 (98%, CAS #106-24-1, Aldrich), 3-octanol (99%, CAS #589-98-0, Aldrich), decanol
263 (99%, CAS #112-30-1, Fluka), 11-Al (99%, CAS #112-44-7, Aldrich).

Odor collection and chemical analysis

265 Twenty *D. melanogaster* (Dalby), *D. melanogaster* (Canton) (*n* = 10) or 20 *D. simulans*
266 (*n* = 10) unmated female or unmated male flies were placed in a glass aeration
267 apparatus designed for collection of airborne pheromone (effluvia) (51). The flies were
268 held in a glass bulb with a narrow open outlet (ø 1 mm), which prevented them from
269 escaping. A charcoal-filtered air flow (100 mL/min) passed over the flies during 75 min.

270 Fly effluvia were collected on the glass surface, breakthrough was monitored by attaching
271 a 10-cm glass capillary (ø 1 mm) attached to the outlet. After 75 min, flies were
272 removed, 100 ng of heptadecyl acetate (internal standard) was deposited in the glass
273 bulb, which was then rinsed with 50 µl hexane, the solvent was concentrated to 10 µl in
274 Francke vials.

275 Cuticular extracts (n = 5) were obtained by dropping 20 *D. melanogaster* females for 5
276 min in 400 µl hexane containing 100 ng heptadecyl acetate. After 5 min, the extracts
277 were transferred to Francke vials and concentrated to 10 µl before analysis. Fly extracts
278 and volatile collections were stored at -20°C.

279 Oxidation of (*Z,Z*)-7,11-heptacosadiene (7,11-HD) was analysed by dropping 100 ng
280 synthetic 7,11-HD into a 1.5-mL glass vial, at 19°C. Vials were rinsed with 10 µl of
281 hexane, which contained 100 ng heptadecyl acetate as an internal standard, after 15, 30,
282 45, 60 and 75 min (n = 3).

283 Samples were analysed by combined gas chromatography and mass spectrometry (GC-
284 MS; 6890 GC and 5975 MS, Agilent technologies Inc., Santa Clara, CA, USA). Two µl
285 were injected (injector temperature 225°C) splitless (30 s) into fused silica capillary
286 columns (60 m x 0.25 mm), coated with HP-5MS UI (Agilent Technologies Inc., d_f = 0.25
287 µm) or DB-wax (J&W Scientific, Folsom, CA, USA, d_f = 0.25 µm), that were temperature-
288 programmed from 30 to 225°C at 8°C/min. Helium was used as mobile phase at 35 cm/s.
289 The MS operated in scanning mode over m/z 29-400. Compounds were tentatively
290 identified based on their mass spectra and Kovats retention indices, using custom and
291 NIST (Agilent) libraries, followed by comparison with authentic standards.

Behavioural assays

293 Upwind flight behavior was observed in a glass wind tunnel (30 x 30 x 100 cm) equipped
294 with a piezo sprayer (40). The flight tunnel was lit diffusely from above, at 13 lux,
295 temperature ranged from 22 to 24°C, relative humidity from 38% to 48% and charcoal
296 filtered air, at a velocity of 0.25 m/s, was produced by a fan (Fischbach GmbH,
297 Neunkirchen, Germany). Compounds were delivered from the centre of the upwind end of
298 the wind tunnel via a piezo-electric micro-sprayer (52). Forty flies were flown individually
299 to each treatment. "Attraction" was defined as upwind flight, directly from a release tube
300 at the end of the tunnel over 80 cm towards the odor source, followed by landing.
301 Unmated fed, 3-d-old Dalby wild-type males and females, *D. melanogaster* Zimbabwe
302 strain males and *D. simulans* males were flown towards (*Z*)-4-undecenal (released at 10
303 ng/min), (*R*)-linalool (10 ng/min) and the blend of (*Z*)-4-undecenal and (*R*)-linalool (10
304 ng/min, each).

Heterologous expression of Or69aA and Or69aB

305
306 Or69aA and Or69aB receptors were cloned from antennae of *D. melanogaster*, Dalby line
307 (53). Briefly, cDNA was generated from RNA extracts of antennae of 100 males and
308 females using standard procedures. Or69a variants were PCR amplified with the following
309 primers: Or69aA_5': GTCATAGTTGAAACCAGGATGCAGTTGC, Or69aB_5':
310 ATAATTCAGGACTAGATGCAGTTGGAGG, Or69aAB_3':
311 TGCACTTTTGCCCTTTTATTTAAGGGAC.

312 The splice variants were amplified with unique 5' primers and a common 3' primer,
313 reflective of genomic structure at this locus. These primers encompass the entire open
314 reading frame of the receptor variants, and are located partially upstream and
315 downstream of the start and stop codons. PCR amplicons were gel-purified and cloned
316 into the pCR8/GW/Topo-TA Gateway entry vector (Thermo-Fisher Scientific, Waltham,
317 MA, USA) according to standard procedure, with vector inserts sequenced to confirm
318 fidelity of Or sequence. Or inserts were subsequently transferred to pUAS.g-HA.attB (54)
319 with LR Clonase II enzyme (Thermo-Fisher Scientific), according to manufacturers
320 protocol; vector inserts were sequenced to confirm fidelity of Or sequence.

321 Mini-prep purified pUAS.g-HA.attB plasmid with Or69aA or Or69aB insert were delivered
322 to Best Gene Inc. (Chino Hills, CA USA) for generation of transgenic *D. melanogaster*
323 flies. Using the PhiC31 targeted genomic-integration system (54) vectors with Or69aA or
324 Or69aB were injected into the following fly strain, for integration on the 3rd chromosome:
325 M{3xP3-RFP.attP}ZH-86Fb (with M{vas-int.Dm}ZH-2A) (Bloomington *Drosophila* Stock
326 Number: 24749). For expression of single receptor variants in the empty neuron system,
327 Or69a transgenes were crossed into the *Δhalo* background to give genotype: w;
328 *Δhalo*/Cyo; UAS-DmelOr69a(A or B), and these flies were crossed to flies with genotype:
329 w; *Δhalo*/Cyo; DmelOr22a-Gal4, as described previously (53). Experimental
330 electrophysiology assays were performed on flies with genotype: w; *Δhalo*; UAS-
331 DmelOr69a(A or B)/DmelOr22a-Gal4.

332 For co-expression of Or69aA and Or69aB in the same empty neurons, a second fly-line
333 with Or69aB was generated with Or69aB present on the X-chromosome. The same UASg-
334 HA.attB:Or69aB plasmid generated previously was injected into the following fly strain:
335 y,w, P{CaryIP}su(Hw)attP8 (Bloomington *Drosophila* Stock Number: 32233). The Or69aB
336 transgene was crossed into the DmelOr22a-Gal4 line in *Δhalo* background to give
337 genotype: UAS-DmelOr69aB; *Δhalo*/Cyo; DmelOr22a-Gal4; these flies were crossed to
338 flies with genotype: w; *Δhalo*/Cyo; UAS-DmelOr69aA. Experimental electrophysiology
339 assays were performed on flies with genotype: UAS-DmelOr69aB/w; *Δhalo*; UAS-
340 DmelOr69aA/DmelOr22a-Gal4.

Conformational analysis

MacroModel version 11.0 (Schrodinger LLC, New York, NY, USA) in the Maestro Version 10.4.017 were used to build, minimize and to perform conformational analysis of *Z4-11Al*, (*R*)-carvone, (*S*)-terpineol and (*R*)-linalool, using default settings (OPLS3 as force field, water as the solvent and mixed torsional/low-mode sampling method). The assumed bioactive conformations of the conformationally more flexible compounds, *Z4-11Al* and (*R*)-linalool, were based on the positon of the shared functional groups in the conformationally more restricted compounds, (*R*)-carvone and (*S*)-terpineol. The carbonyl and the double bond atoms were kept fixed during minimization of the proposed bioactive conformation of Z4-11Al; the alcohol functional group and the double bond were kept fixed in (*R*)-linalool. The strain energies, the energy cost for adopting proposed bioactive conformations, were then calculated as the difference between the lowest energy conformations and the assumed bioactive conformation.

Electrophysiological recordings

Single sensillum recordings (SSR) were done as described earlier ([19]). Unmated males were restrained in 100-µl pipette tips, with half of the head protruding, the third antennal segment or palps were placed on a glass microscope slide and held by dental wax. For the initial screening, all basiconic, trichoid, coeloconic, and intermediate sensilla ([31]) were localized in *D. melanogaster* (Canton-S strain) males, under a binocular at 1000x magnification. Further recordings were made from small basiconic ab9 sensilla, in *D. melanogaster* (Canton-S and Zimbabwe strains) and in *D. simulans* males, and from large basiconic ab3 sensilla in mutant *D. melanogaster*, where Or69aA and Or69aB were heterologously expressed (see above).

Tungsten electrodes (diameter 0.12 mm, Harvard Apparatus Ltd, Edenbridge, United Kingdom) were electrolytically sharpened with a saturated KNO_3 solution. The recording electrode was introduced with a DC-3K micromanipulator equipped with a PM-10 piezo translator (Märzhäuser Wetzler GmbH, Germany) at the base of the sensilla. The reference electrode was inserted into the eye. The signal from olfactory sensory neurons (OSNs) was amplified with a probe (INR-02; Syntech), digitally converted by an IDAC-4-USB (Syntech) interface, and analyzed with Autospike software v. 3.4 (Syntech). Neuron activities were recorded during 10 s, starting 2 s before odor stimulation. Neuron responses were calculated from changes in spike frequency, during 500 ms before and after odor stimulation.

Odorants were diluted in redistilled hexane, 10 µg of test compounds in 10 µl hexane were applied to filter paper (1 cm^2), kept in Pasteur pipettes. The test panel contained the most active ligands known for Or69a ([30]) and several aldehydes. Diagnostic compounds for confirmation of sensillum identity were 2-phenyl ethanol (ab9) and 2-heptanone (ab3). Control pipettes contained solvent only. Puffs (2.5 ml, duration 0.5 s)

379 from these pipettes, produced by a stimulus controller (Syntech GmbH, Kirchzarten,
380 Germany), were injected into a charcoal-filtered and humidified airstream (0.65 m/s),
381 which was delivered through a glass tube to the antenna.

382 For GC–SSR recordings, GC columns and the temperature programmes were the same as
383 for the GC–MS analysis. At the GC effluent, 4 psi of nitrogen was added and split 1:1 in a
384 3D/2 low dead volume fourway-cross (Gerstel, Mühlheim, Germany) between the flame
385 ionization detector and the antenna. Towards the antenna, the GC effluent capillary
386 passed through a Gerstel ODP-2 transfer line, that tracked GC oven temperature, into a
387 glass tube (30 cm x 8 mm ID), where it was mixed with charcoal-filtered, humidified air
388 (20°C, 50 cm/s).

Statistical analysis

390 Generalized linear models (GLM) with a Bernoulli binomial distribution were used to
391 analyse wind tunnel data. Landing at source and sex were used as the target effects.
392 *Post-hoc* Wald pairwise comparison tests were used to identify differences between
393 treatments. For all the electrophysiological tests, differences in spike activity derived from
394 SSRs were analyzed with Kruskall Wallis H test followed by pairwise comparisons with
395 Mann Whitney U *post hoc* test. All statistical analysis were carried out using R (R Core
396 Team 2013) and SPSS Version 22 (IBM Corp.).

Acknowledgements

Author Contributions

561   S.L., P.G.B. and P.W. conceived the study. F.B.-E and M.S. carried out behavioural

562   studies, F.G. and W.B.W produced empty neuron flies, F.G. and H.D. did single sensillum

563   recordings, supervised by B.S.H, E.W. and E.H. synthesized the compound, A.-L.G.

564   calculated the confirmational analysis, M.B., G.B. and S.L. performed chemical analysis,

565   P.W. wrote the paper with input from all co-authors.

Legends

Figure 1. Headspace analysis of *Drosophila* females and males by GC-MS and electrophysiological screening of the candidate pheromone compound *Z*4-11Al on male antennae.

(**a**) Chromatograms of headspace collections from *D. melanogaster* females (lilac traces; upper trace: amplified signal; lower trace: entire chromatogram), males (blue trace), and *D. simulans* females (green trace). The headspace of *D. melanogaster* females contains 16 yet undescribed compounds: heptanal (*1*), octanal (*2*), (*Z*)4-nonenal (*3*), nonanal (*4*), (*Z*)4-undecenal (*Z*4-11Al) (*5*), undecanal (*6*), dodecanal (*7*), (*Z*)4-tridecenal (*8*), tridecanal (*9*), tetradecanal (*10*), pentadecanal (*11*), (*Z*)4-hexadecenal (*12*), hexadecanal (*13*), (*Z*)4-octadecenal (*14*), octadecanal (*15*) and (*Z*)4-eicosenal (*16*) (see Table 1). Female-specific compounds are coloured, the most abundant cuticular hydrocarbon, 7-tricosene (*17*) is shown for reference, the internal standard (IS) was heptadecyl acetate. Inset: mass spectrum of the most abundant female-specific compound *Z*4-11Al.

(**b**) Oxidation of the most abundant female cuticular hydrocarbon (*Z*,*Z*)-7,11-heptacosadiene (7,11-HD), affording two saturated and two unsaturated aldehydes, heptanal, hexadecanal, *Z*4-11Al and (*Z*)4-eicosenal.

(**c**) Single sensillum recordings (SSR) from all *D. melanogaster* olfactory sensory neurons (OSNs) with *Z*4-11Al (error bars show SEM; $n = 5$).

(**d**) SSR coupled to GC (GC-SSR), showing a response of ab9A to three different amounts of *Z*4-11Al.

Figure 2. SSR-Response of Or69a splice variants to ten odorants, in native ab9A OSNs and in ab3A OSNs, following heterologous expression.

(**a**) SSR from ab9A OSNs, in *D. melanogaster* (Canton-S, Zimbabwe) and *D. simulans* males, which natively express both splice variants Or69aA and Or69aB. Responses were normalized to the most active odorant.

(**b**) SSR from ab3A OSNs in *D. melanogaster,* heterologously expressing Or69aA and Or69aB, together and singly. Test panel includes the known most active ligands for Or69a (27) and three aldehydes. Cross-hatched bars indicate behaviorally active compounds (Fig. 3). Bars followed by different letters indicate statistically significant differences for each fly type ($P<0.05$; Mann-Whitney test, $n = 5$ for ab9A, $n = 10$ for ab3A).

(**c**) Key ligands for Or69aA, (*S*)-terpineol (*1*) and (*R*)-linalool (*4*), and for or Or69aB, (*R*)-carvone (*8*) and Z4-11Al (*10*). Alignment of these ligands illustrates shared structural motifs.

600   (**d**) Alternative splicing of Or69a, where coloured boxes A and B show unique exons

601   encoding the splice products; dark boxes show shared exons, generating co-expression of

602   Or69aA and Or69aB in the same neurons in ab9 sensilla in *D*. *melanogaster*.

603   **Figure 3. Z4-11Al mediates long range attraction in *D. melanogaster*.**

604   (**a**) Upwind flights to 10 ng/min of *Z*4-11Al and (*R*)-linalool, followed by landing at the

605   source, in *D. melanogaster* (Dalby) males and females, in *D. melanogaster* (Zimbabwe)

606   males and *D. simulans* males. Lower case letters indicate statistical differences between

607   test insect strains and species, for each treatment. Asterisks indicate significant

608   differences between treatments ($n = 40$, $P<0.001$; binomial GLMs followed by post-hoc

609   Wald pairwise comparison tests).

610   (**b**) Upwind flights to 10 ng/min of *Z*4-11Al and (*R*)-linalool in *D. melanogaster* (Canton-

611   S) males expressing a tetanus toxin in OSNs expressing Or69a, and in the parental lines.

612   Letters indicate statistical differences within treatments ($n = 40$, $P<0.001$; binomial GLM,

613   followed by *Post-hoc* Wald pairwise comparison tests).

614

Supplementary Information: Chemical Synthesis

Dry THF and dry Et_2O was obtained from a solvent purification system (Activated alumina columns, Pure Solv PS-MD-5, Innovative technology, Newburyport, USA) and used in the reactions when dry conditions were needed. All other chemicals were used without purification. Reactions were performed under Argon atmosphere unless otherwise stated. Flash chromatography was performed on straight-phase silica gel (Merck 60, 230–400 mesh, 0.040–0.063 mm, 10–50 g/g of product mixture) employing a gradient technique with an increasing concentration (0–100 %) of distilled ethyl acetate in distilled cyclohexane. In cases of very polar products chromatography was continued with ethanol in ethyl acetate (0-20 %). Thin-layer chromatography (TLC) was performed to monitor the progress of the reaction on silica gel plates (Merck 60, precoated aluminium foil), using ethyl acetate (40 %) in cyclohexane as an eluent, and plates were developed by means of spraying with vanillin in sulfuric acid and heating at 120°C. Purity of the product was checked with gas chromatography (GC) analysis on a Varian 3300 GC instrument equipped with a flame ionization detector (FID) using a capillary column Equity-5 (30 m x 0.25 mm i.d, d_f = 0.25 μm, with nitrogen (15 psi) as carrier gas and a split ratio of 1:20). The oven temperature was programmed at 50°C for 5 min followed by a gradual increase of 10°C min^{-1} to reach a final temperature of 300°C. An Agilent 7890 GC equipped with a polar capillary column FactorFOUR vf-23ms (30 m x 0.25 mm i.d., d_f = 0.25 μm) coupled to an Agilent 240 ion-trap MS detector for separation of some isomeric intermediates. The injector was operated in split mode (1:20) at 275°C, and a helium flow rate of 1 ml min^{-1} and a transfer line temperature of 280 °C. The analyses were performed in the external ionisation configuration. EI spectra were recorded with a mass range of m/z 50-300 at fast scan rate. Nuclear magnetic resonance (NMR) spectra were recorded on a Bruker Avance 500 (500 MHz ^{1}H, 125.8 MHz ^{13}C) spectrometer using $CDCl_3$ as solvent and internal standard.

(*Z*)-4-Undecenoic acid. NaHMDS (6.78 mmol, 1 M in hexane) was added dropwise, during 30 min, to a suspension of (3-carboxypropyl)triphenylphosphonium bromide (1.45 g, 3.39 mmol) in THF (25 mL). The mixture was stirred for 2 h then cooled to 0°C on ice/water bath, and heptanal (0.387g, 3.39 mmol) in THF (2.5 mL) was added slowly during 15 min. The mixture was stirred for 5 h at 0°C then allowed to reach room temperature over night. The reaction was quenched with H_2O (20 mL) and the organic solvent was evaporated. The remaining water phase was extracted with Et_2O (3 x 20 mL), the obtained organic phases discarded and the basic aqueous phase was acidified with HCl (2M) until pH 1 and extracted with Et_2O (3 x 20 mL). The combined organic phases were dried over $MgSO_4$ (anhydr.) and the solvent evaporated off. The obtained crude product was dissolved in pentane, cooled at -18°C and filtered to remove the precipitated $OPPh_3$ followed by evaporation of the solvent to result in 0.547 g of a yellow oil (87.5% yield). ^{1}H-NMR: 5.52–5.30 (m, 2H), 2.35 (m, 4H), 2.04 (q, *J* = 6.5 Hz, 1.6H,

659   *Z*-isomer), 1.96 (q, *J*=6.5 Hz, 0.4H, *E*-isomer), 1.37–1.19 (m, 8H), 0.89 (t, *J*=7 Hz, 3H)

660   ppm. The NMR data is in accordance with data previously reported (46, 52). The

661   relationship by integration between protons at 2.04 and 1.95 indicates approximately a

662   *Z*:*E*-ratio of 80:20 which is supported by GC-MS analysis on a Varian factorFOUR vf-23ms

663   column. The obtained crude product was used in the next step without further

664   purification.

665   **Methyl (*Z*)-4-undecenoate**. (*Z*)-4-Undecenoic acid (0.547 g, 2.97 mmol) from above

666   was dissolved in methanol (15 mL) and 7 drops of concentrated H_2SO_4 were added

667   followed by heating at 70°C over night. The mixture was allowed to reach room

668   temperature and the methanol was evaporated and the remaining crude product was

669   dissolved in Et_2O (15 mL). The organic phase was washed with H_2O (3 x 10 mL) and brine

670   (2 x 10 mL), dried over Na_2SO_4 (anhydr.) and solvent evaporated resulting in 0.547 g of

671   a yellow oil (92.8% yield). GC-MS (FactorFour vf-23ms) shows a *Z*:*E*-ratio of 80:20. [1]H-

672   NMR($CDCl_3$): 5.4 (m, 2H), 3.67 (s, 3H), 2.3 (m, 4H), 2.03 (q, *J* = 6.5 Hz, 1.6H, *Z*-

673   isomer), 1.96 (q, *J*=6.5 Hz, 0.4H, *E*-isomer), 1.33–1.21 (m, 8H), 0.89 (t, *J*=6.5 Hz, 3H)

674   ppm (no data found in the literature). ^{13}C-NMR($CDCl_3$): 134.2, 119.9, 32.3, 31.9, 29.5,

675   29.3, 27.43, 22.7, 14.1 ppm. ^{13}C-NMR data similar to reported (53). Proton NMR shows a

676   80:20 *Z*:*E*-ratio between the diastereomers. Enrichment of the *Z*-isomer on $AgNO_3$ (10%)

677   impregnated silica resulted in 63 mg of 98.6:1.4 *Z*:*E*-ratio according to GC-FID analysis

678   on the vf-5 column as the diastereoisomeric purity was not possible to measure when

679   using ^{1}H-NMR.

680   **(*Z*)-4-Undecenol**. Methyl (*Z*)-4-undecenoate (63 mg, 0.32 mmol) was dissolved in Et_2O

681   (5 mL) and $LiAlH_4$ (2 spatel tips) was added followed by stirring at room temperature for

682   30 min. HCl (2 M, 2 mL) was added to quench the reaction and the mixture was extracted

683   with Et_2O (2 x 3 mL), the combined organic layer was dried over $MgSO_4$ (anhydr.) and

684   solvent was evaporated. Purification with flash chromatography on SiO_2 resulted in 37

685   mg. ^{1}H-NMR($CDCl_3$): 5.43-5.32 (m, 2H), 3.67 (m, 2H), 2.16–2.10 (m, 2H), 2.08–2.02

686   (m, 2H), 1.69–1.60 (m, 2H), 1.39–1.22 (m, 8H), 0.89 (t, *J*=6.5 Hz, 3H) ppm. NMR-data

687   were similar to Kim and Hong (54) and Davis and Carlsson (55). Diastereomeric purity

688   was checked with GC-FID before next step.

689   **(*Z*)-4-Undecenal**. (*Z*)-4-Undecenol (37 mg, 0.22 mmol) in DCM (3 mL) was added to

690   Dess-Martin periodinane (0.140 g, 0.33 mmol) in DCM (0.5 mL). After 50 min, NaOH

691   (2M, 10 mL) was added to quench the reaction. The two layers were separated and the

692   aqueous phase was extracted with Et_2O (3 x 10 mL), the combined organic layers were

693   washed with NaOH (2M, 10 mL), dried over $MgSO_4$ (anhydr.) and solvent was evaporated

694   resulting in 30 mg of a yellow oil (81% yield). The crude product was purified with

695   Kugelrohr distillation at bp 65–70 °C (1.6 mbar), resulted in 17 mg. ^{1}H-NMR($CDCl_3$): 9.77

696   (s, 1H), 5.48–5.22 (m, 2H), 2.47 (t, *J* = 7 Hz, 2H), 2.37 (q, *J* = 7 Hz, 2H), 2.04 (q, *J* =

697   7Hz, 2H), 1.37–1.23 (m, 8H), 0.88 (t, *J* = 7 Hz, 3H) ppm. ^{13}C-NMR($CDCl_3$): 202.1, 131.8,

698   127.0, 43.9, 31.8, 29.5, 29.0, 27.2, 22.6, 20.1, 14.1 ppm. Both ^{1}H- and ^{13}C-NMR data

699   were in accordance with published results (56, 57). Analysis on GC-MS (FactorFour vf-

700   23ms) resulted in a 98.6:1.4 *Z*:*E*-ratio, the *E*-isomer could not be detected by ^{1}H-NMR.

701   **(*E*)-4-Undecenoic acid**. 4-Pentenoic acid (0.5 g, 5 mmol) and 1-octene (2.8 g, 25

702   mmol) was dissolved in DCM (50 mL) and Grubbs II catalyst (85 mg, 0.1 mmol) was

703   added and the reaction was refluxed. After 7 h was a second portion of Grubbs II catalyst

704   (85 mg, 0.1 mmol) added and the reaction refluxed for 16 h. Reaction was allowed to

705   reach room temperature and the solvent was evaporated. The obtained crude product

706   was dissolved in Et_2O (50 mL) and filtered through a short pad of silica gel. The product

707   was purified with flash chromatography by gradient elution (0–100% EtOAc in c-hexane

708   followed by 0–10% EtOH in EtOAC) resulting in 0.52 g oil (56% yield). ^{1}H-NMR($CDCl_3$):

709   5.51–5.33 (m, 2H), 2.41 (q, *J*=7 Hz, 2H), 2.32 (q, *J*=7 Hz, 2H), 2.04 (q, *J*=6.5 Hz, 0.25

710   H, *Z*-isomer), 1.97 (q, *J*=6.5 Hz, 1.75H, *E*-isomer), 1.37–1.22 (m, 9H), 0.88 (t, *J*=7.5

711   Hz, 3H) ppm. The relation between proton at 2.04 and 1.97 reveals a 87.5:12.5 *E*:*Z*-

712   ratio. The isolated product was used in the next step without further purification.

713   **Methyl (*E*)-4-Undecenoate**. (*E*)-4-Undecenoic acid (0.52 g, 2.82 mmol) was dissolved

714   in methanol (25 mL) and a catalytic amount H_2SO_4 was added and the mixture was

715   refluxed over night. After evaporation of the solvent the crude product was dissolved in

716   Et_2O (10 mL) and washed with H_2O (20 mL). The aqueous phase was extracted with Et_2O

717   (2 × 25 mL), the combined organic layer was washed with H_2O (20 mL) and brine (20

718   mL), dried over $MgSO_4$ (anhydr.) and evaporation of solvent resulted in 0.439 g (78%

719   yield). ^{1}H-NMR($CDCl_3$): 5.51–5.33 (m, 2H), 3.67 (s,3H), 2.40–2.27 (m, 4H), 1.96 (q,

720   *J*=6.5 Hz, 2H), 1.38–1.21 (m, 8H), 0.88 (t, *J*=6.5 Hz,3H) ppm. Purification with flash

721   chromatography resulted in 0.401g (71.7% yield). GC-FID showed the same

722   stereoisomeric ratio as for the acid above.

723   **(*E*)-4-Undecen-1-ol**. $LiAlH_4$ (0.055 g, 1.46 mmol) was added to methyl (*E*)-4-

724   undecenoate (0.145 g, 0.73 mmol) dissolved in Et_2O (5 mL). After 30 minutes was HCl (2

725   M, 5 mL) added to quench the reaction. The acidic water phase was extracted with Et_2O

726   (3 × 10 mL) and the combined organic layers were dried over $MgSO_4$ (anhydr.) and

727   evaporation of solvent resulted in 0.104 g (99% yield). Enrichment of the *E*-isomer with

728   medium pressure liquid chromatography (MPLC) on $AgNO_3$ (10% impregnated) silica

729   resulted in 30 mg of a clear oil (>99.8 % *E*). ^{1}H-NMR($CDCl_3$): 5.43 (m, 2H), 3.65 (m,

730   2H), 2.08 (q, *J*=7 Hz, 2H), 1.97 (q, *J*=7 Hz, 2H), 1.63 (pent, 2H), 1.35–1.21 (m, 9H),

731   0.88 (t, *J*=6.5 Hz, 3H) ppm. ^{13}C-NMR($CDCl_3$): 134.4, 131.3, 129.4, 62.6, 32.6, 32.5,

732   31.7, 29.6, 29.5, 28.9, 28.8, 22.6, 14.1 ppm. All NMR-data were in accordance with

733   previous published data (58).

734   **(*E*)-4-Undecenal**. Dess-Martin Periodinane (0.110 g, 0.26 mmol) was added to (*E*)-4-

735   undecen-1-ol (0.030 g, 0.22 mmol) in DCM (4 mL). NaOH (2 M, 10 mL) was added after

736   1 h to quench reaction. The aqueous phase was extracted with Et_2O (3 × 10 mL) and the

737 combined organic layers were dried over MgSO$_4$ (anhydr.) and evaporation of the solvent
738 resulted in 30 mg (98% yield). Purification of the crude with Kugelrohr distillation at 65°C
739 (2 mbar) resulted in 10 mg of product (33% yield, 97% chemical purity, 3% undecenal).
740 ^{1}H-NMR(CDCl$_3$): 9.76 (t, J=1.5 Hz, 1H), 5.50–5.36 (m, 2H), 2.48 (d of t, J=7.5, 1.5 Hz,
741 2H), 2.33 (q, J=7 Hz, 2H), 1.97 (q, J=6.5 Hz, 2H), 1.32–1.19 (m, 8H), 0.87 (t, J=6.5 Hz,
742 3H). ^{13}C-NMR (CDCl$_3$): 202.5, 132.2, 127.6, 43.6, 32.5, 31.7, 29.4, 28.8, 25.2, 22.6,
743 14.1. The NMR-data were in accordance with published data (57, 58).

744 (*Z*)-4-Undecenoic acid was synthesized via a modified version of Wube and Hüfner (46) in
745 80% stereoisomeric purity. Esterification under acidic conditions with sulfuric acid in
746 methanol resulted in 80% *Z*-isomer and a 93% yield over two steps. Stereoisomeric
747 purity was controlled with NMR and GC-FID by comparing analysis for acid and ester, the
748 appearance of a small quartet, in the NMR spectra, at 1.96 indicates the presence of *E*-
749 isomer. Gas chromatographic separation on a polar Varian factorFOUR vf-23ms of *Z*- and
750 *E*-ester proved that the stereochemistry was not affected by the acidic conditions during
751 esterification. Methyl-(*Z*)-4-undecenoate was purified on regular silica gel and on silver
752 nitrate impregnated silica gel to obtain a stereoisomeric purity of 98.6 %. Methyl-(*Z*)-4-
753 undecenoate was reduced to (*Z*)-4-undecenol with lithium aluminum hydride in
754 diethylether and oxidized to (*Z*)-4-undecenal with Dess-Martin periodinane in
755 dichloromethane.

756 A modified version of Virolleaud´s (47) metathesis was used to produce the (*E*)-4-
757 undecenoic acid and in a 56 % yield (87.5% of the *E*-isomer). (*E*)-4-undecenoic was
758 esterified under the same conditions as the (*Z*)-acid and once again there was no
759 isomerisation of the double bond (according to GC-FID and ^{1}H-NMR. The methyl-(*E*)-4-
760 undecenoate was reduced to alcohol with LiAlH$_4$ in diethylether and purified on silver
761 nitrate impregnated silica gel to obtain a purity of 99.8 % of the (*E*)-isomer, which was
762 oxidized with Dess-Martin periodinane in dichloromethane to obtain the wanted (*E*)-4-
763 undecenal.
