26 ABSTRACT

27   Acidification of secretory and endocytic organelles is required for proper receptor recycling,

28 membrane traffic, protein degradation, and solute transport. Proton-pumping vacuolar ATPases

29 (V-ATPases) are responsible for this luminal acidification, which increases progressively as

30 secretory and endocytic vesicles mature. An increasing density of V-ATPase complexes is

31 thought to account for the gradual decrease in pH, but available reagents have not been

32 sufficiently sensitive nor specific to test this hypothesis. We introduce a new probe to localize

33 and quantify V-ATPases in eukaryotic cells. The probe is derived from SidK, a *Legionella*

34 *pneumophila* effector protein that binds to the V-ATPase A subunit. We generated plasmids

35 encoding fluorescent chimeras of SidK$_{1\text{-}278}$, and labeled recombinant SidK$_{1\text{-}278}$ with AlexaFluor-

36 568 to visualize and quantify V-ATPases with high specificity in live and fixed cells, respectively.

37 We show that V-ATPases are acquired progressively during phagosome maturation, that they

38 distribute in discrete membrane subdomains, and that their density in lysosomes depends on

39 the subcellular localization of the lysosome.

40

41 INTRODUCTION

42   The steady-state pH of individual cellular compartments is a key determinant of their

43 function and must be regulated stringently. Indeed, the luminal pH directs receptor recycling and

44 membrane traffic, regulates protein degradation, and contributes to the transmembrane

45 protonmotive force that drives the transport of a variety of organic and inorganic solutes

46 (Maxfield and McGraw, 2004; Saftig and Klumperman, 2009; Fisher and Scheller, 1988; Huotari

47 and Helenius, 2011). It is therefore not surprising that dysregulation of organellar pH has been

48 implicated in various human diseases such as cancer, neurological disorders, osteoporosis, and

49 autoimmunity (Marshansky et al., 2014; Capecci and Forgac, 2013; Colacurcio and Nixon,

50 2016; Sun-Wada et al., 2006; Eaton et al., 2021).

51   Most endocytic and secretory organelles maintain an acidic lumen, with acidification

52 increasing progressively as these organelles approach their terminal stages (Mellman et al.,

53 1986). Thus, the endocytic pathway progresses from slightly acidic early endosomes (pH 6.5) to

54 highly acidic lysosomes (pH 4 to 5). The main driver of organellar acidification is the

55 ATP-dependent proton pump known as the vacuolar H^+-ATPase (V-ATPase). The V-ATPase is

56 present in vesicular membranes of the endocytic and secretory pathways, and is also found in

57 the plasma membrane of specialized cell types involved in the active extrusion of cytosolic

58 protons, such as osteoclasts and renal intercalated cells (Toei et al., 2010; Futai et al., 2019).

59 The V-ATPase is a large rotary complex with 16 different subunits in mammals. ATP-hydrolysis

60 occurs in the soluble catalytic V_1 region (subunits A to H), driving rotation of the enzyme's rotor

61 subcomplex and proton translocation through the V_O regions (subunits a, d, e, f c, c□,

62 ATP6AP1/Ac45, and ATP6AP2/PRR; Abbas et al., 2020). V-ATPase activity is regulated by

63 several mechanisms, including reversible dissociation of the V_1 and V_O regions (Tabke et al.,

64 2014; Kawasaki-Nishi, 2001; Parra and Kane, 1998; Poëa-Guyon et al., 2013), phosphorylation

65 (Voss et al., 2007; Alzamora et al., 2010), and changes in membrane lipid composition

66 (Banerjee et al., 2019; Vasanthakumar et al., 2019; Uchida et al., 1985).

67   Several parameters determine the steady-state pH of the lumen of an organelle. Because

68   proton pumping by V-ATPase is electrogenic, the rate of pumping can be limited by the

69   permeability of the membrane to neutralizing counter ions. In addition, the accumulation of

70   protons is opposed by ongoing proton backflux or "leak" via a collection of incompletely

71   characterized channels and transporters. A final fundamental parameter is the density of V-

72   ATPase complexes in the membrane of any particular organelle. It has been tacitly assumed

73   that V-ATPase density increases progressively as the components of endocytic and secretory

74   pathways mature and become more acidic. However, this assumption has not been validated

75   for two main reasons. First, it is difficult to isolate individual stages of these pathways with

76   sufficient purity for reliable biochemical analysis. Second, reagents with sufficient resolution and

77   accuracy are lacking for localization and quantification of V-ATPase in cells. Several antibodies

78   to different V-ATPase subunits are available commercially and some of them have yielded

79   satisfactory results in histological analyses, especially of tissues like the kidney where

80   specialized cell types are uniquely enriched in V-ATPases. However, these same antibodies

81   show poor specificity and a low signal-to-noise ratio when used to stain non-specialized single

82   cells, which have a lower abundance of V-ATPases. The interpretation of the resulting

83   immunostaining can be ambiguous, confounding the results.

84   The paucity and unsatisfactory performance of reagents currently available to study the V-

85   ATPase motivated us to develop a novel tool for its specific intracellular labeling in eukaryotic

86   cells. To this end we took advantage of SidK, an effector protein deployed by *Legionella*

87   *pneumophila* to inhibit the V-ATPase (Xu et al., 2010). SidK was recently shown to bind directly

88   to yeast and mammalian V-ATPases by (Zhao et al., 2017; Abbas et al., 2020), allowing use of

89   the effector to purify proton pumps from tissue extracts (Abbas et al., 2020). In this study, we

90   describe the generation and labeling of a recombinant fragment of SidK and its use to localize

91   and quantify V-ATPases in eukaryotic cells with high sensitivity and specificity. We utilized this

92   reagent to study the distribution of the V-ATPase in various cell types, and to monitor its

93   acquisition by membrane-bound compartments as they mature along the endocytic pathway.

94   Lastly, we used SidK to estimate the number of V-ATPase complexes in individual

95   compartments as a function of their position within the cell.

96

97   RESULTS

98   **Generation of fluorescent SidK chimeras for expression in mammalian cells**

99   SidK was reported to bind with high affinity to the A subunit of the V-ATPase (Xu et al.,

100   2010; Sharma and Wilkens, 2017; Abbas et al., 2020; Zhao et al., 2017). We reasoned that the

101   *Legionella* effector would be an effective probe to visualize V-ATPase by fluorescence

102   microscopy. To this end we generated chimeric constructs consisting of amino acids 1 to 278 of

103   SidK (SidK$_{1-278}$) attached to a fluorescent protein (GFP or mCherry) with a linker sequence.

104   SidK$_{1-278}$ suffices to interact with the A subunit with high specificity; indeed, this fragment was

105   used for the affinity purification of V-ATPases from cell and tissue extracts (Fig. 1A; see also

106   Abbas et al., 2020). GFP or mCherry were linked to SidK$_{1-278}$ via its C terminus because the

107   structure of the V-ATPase:SidK$_{1-278}$ complex suggested that attachment at this position was

108   unlikely to affect association of the chimera with the V-ATPase (Fig. 1B; Abbas et al., 2020). For

109   brevity, the resulting construct is referred to simply as SidK.

110   As is often the case, varying levels of expression were observed following transient

111   transfection of fluorescent SidK in HeLa cells. The fluorescence intensity of the soluble (excess)

112   SidK seen in high expressers (SidK$_{high}$) precluded the resolution of the fraction of the construct

113   bound to V-ATPase-containing organelles, such as lysosomes (Fig. 1C). In contrast, SidK

114   showed clear association with vesicular and tubular structures in low-expressing cells (SidK$_{low}$,

115   Fig. 1D), some of which were identifiable as lysosomes by loading with fluorescent dextran.

116   Because the excess fluorescence of SidK$_{high}$ cells appeared to be cytosolic, we predicted that

117   selective removal of soluble material would reveal the more tightly-bound, organelle-associated

118   probe. This assumption was tested by comparing SidK$_{high}$ cells before (Fig. 1E) and after (Fig.

119   1F) selective leaching of cytosolic components following permeabilization of the plasma

120   membrane with the pore-forming toxin, pneumolysin (PLY). As anticipated, the cytosolic

121   fluorescence was largely depleted in PLY-treated cells, revealing membrane-associated SidK, a

122   fraction of which was clearly co-localized with LAMP1, a marker of late endosomes/lysosomes.

123   We concluded that the fluorescent chimeras of SidK can be used for detection of membrane-

124   associated ligands, presumably V-ATPases, particularly in cells with low expression level or

125   permeabilized with PLY or similar reagents.

126

127   **Expression of SidK-fluorescent protein constructs affects lysosomal positioning and pH**

128   In otherwise untreated HeLa cells late endosomes/lysosomes are largely located near the

129   nucleus, as revealed by LAMP1 immunostaining (Fig. 2A). However, we noted that

130   endo/lysosomes tended to accumulate at the cell periphery of SidK-transfected cells, particularly

131   those where the construct was highly expressed (Fig. 2B; see also 1F). Because SidK has been

132   shown to inhibit the V-ATPase partially both *in vitro* and in mammalian cells (Zhao et al., 2017;

133   Xu et al., 2010), we considered the possibility that inhibition of proton pumping was responsible

134   for the altered distribution of LAMP1-positive compartments. This notion was validated by

135   treating cells with concanamycin A, a potent and specific V-ATPase inhibitor, which resulted in a

136   similar margination of a fraction of the LAMP1-positive compartments (Fig. 2C). These

137   observations are consistent with previous reports that the positioning of lysosomes correlates

138   with their luminal pH (Johnson et al., 2016).

139   To verify that SidK caused lysosomal alkalinization we used cresyl violet (Ostrowski et al.,

140   2016), an acidotropic fluorescent dye that is more photostable than the LysoTracker dye used

141   by Xu et al. (2010). Unexpectedly, and in apparent disagreement with the findings of Xu et al.

142   (2010), the lysosomes remained acidic (retained cresyl violet) despite the presence of SidK in

143   the cytosol (Fig. 2D). The reliability of cresyl violet as an indicator of lysosomal acidification was

144   confirmed using concanamycin A, which prevented the accumulation of the acidotropic dye (Fig.

145   2E). It is noteworthy, however, that like other acidotropic dyes, cresyl violet is a coarse indicator

146   of pH, unable to sense moderate changes in pH. In this regard, it is of interest that *in vitro*

147   determinations using purified yeast V-ATPase showed that saturating concentrations of SidK

148   caused only a ≈30% inhibition of ATPase activity (Zhao et al., 2017). To more precisely assess

149   the effect of SidK expression on HeLa cells, their lysosomes were loaded with FITC-dextran and

150   pH was measured ratiometrically *in situ* (see Materials and Methods). Using this approach, the

151   pH of lysosomes in SidK-expressing cells was found to be moderately –yet significantly– more

152   alkaline (pH 5.22 ± 0.12) than that of control cells (pH 4.97 ± 0.07; Fig. 2F). As discussed

153   above, a variety of parameters influence the steady-state luminal pH of an organelle. Therefore,

154   we endeavored to more directly assess the effect of SidK on proton pumping by the V-ATPase.

155   This activity can be measured by quantifying the effect of concanamycin on proton flux across

156   the lysosomal membrane. These measurements are based on the assumption that at steady-

157   state pH, V-ATPase activity is precisely offset by an equivalent but opposite backflux (leak) of

158   protons. The initial rate of proton leakage unmasked by addition of saturating concentrations of

159   concanamycin can therefore be considered as an accurate measure of proton pumping by the

160   V-ATPase at steady-state. This analysis (Fig. 2G) indicated that SidK reduced proton pumping

161   by the V-ATPase by 29%, in good agreement with previous *in vitro* measurements (Zhao et al.,

162   2017). Whether the modest change in pH or the more obvious inhibition of the rate of pumping

163   are responsible for the redistribution of lysosomes within the cells remains to be established.

164

165   **Localization of the V-ATPase in mammalian cells using SidK-AL568**

166   The preceding results indicated that, while capable of detecting the V-ATPase under

167   appropriate conditions, expression of a genetically-encoded form of fluorescent SidK had

168   obvious limitations, most notably the fact that chronic inhibition of the pump –even if only

169   partial– alters the distribution of the labeled organelles. To avoid inhibition of the pump prior to

170   its detection we developed an alternative probe based on SidK that could be used to label the

171   V-ATPase in fixed and permeabilized cells. Recombinant SidK$_{1-278}$ was expressed in bacteria

172   and, after purification to near homogeneity (Fig. 1A), was covalently labeled with Alexa Fluor

173   568 (referred to hereafter as SidK-AL568) and used to stain cells. In HeLa cells, SidK-AL568

174   labelled vesicular and cisternal compartments reminiscent of endosomes and the Golgi complex

175   with remarkably little background noise (Fig. 3A, left panel). This staining was blocked by

176   pretreatment with unlabeled SidK (Fig. 3A, right panel), implying that binding is saturable and

177   that Alexa Fluor conjugation did not alter the binding properties of SidK.

178   The specificity of SidK-AL568 for the A subunit of the V-ATPase was validated by comparing

179   staining of wild-type *Saccharomyces cerevisiae* to that of a mutant strain lacking the gene for

180   subunit A (*vma1Δ*). SidK-AL568 clearly labeled the vacuole and pre-vacuolar compartment of

181   wild-type spheroplasts, but staining was absent in the *vma1Δ* strain. Additional evidence that

182   SidK-AL568 associates with assembled V-ATPase complexes in mammalian cells was obtained

183   by ectopic (over)expression in HeLa cells with fluorescently tagged V$_o$a2 or V$_o$a3 subunits that

184   localize predominantly to the Golgi complex or endosomes, respectively (Saw et al., 2011).

185   SidK-AL568 co-localized with both V$_o$a2- and V$_o$a3-GFP, with highly significant Manders'

186   coefficients (M= 0.74 and 0.79, respectively; Figs. 3C and D). Taken together, these data

187   verified that fluorescently labeled SidK is a sensitive tool for the specific detection of the V-

188   ATPase in eukaryotic cells, where it detects primarily organelle-associated complexes.

189   We proceeded to use SidK-AL568 to assess the presence and density of V-ATPase

190   complexes in defined intracellular compartments, an experiment that –while conceptually

191   simple– has been hampered by the paucity of sufficiently sensitive reagents. As intimated above

192   and illustrated in more detail in Fig. 4A, SidK-AL568 stained peripheral vesicular compartments

193   (Fig. 4A, open arrowheads) as well as juxtanuclear vesicles and cisternae (closed arrowheads)

194   likely corresponding to endocytic and Golgi components, respectively. These assumptions were

195   confirmed by simultaneously visualizing LAMP1 and the *trans*-Golgi (Figs. 4B and C),

196   demonstrating that SidK-AL568 staining has a high degree of colocalization with these

8

197 compartments, which are known to have a markedly acidic lumen (Casey et al., 2009). In

198 contrast, SidK-AL568 showed minimal colocalization with markers of the endoplasmic reticulum

199 (ER) and mitochondria (Figs. 4E and F), which have a near-neutral or slightly alkaline lumen

200 (Casey et al., 2009). Of note, SidK-AL568 labeled poorly the *cis*-Golgi (Fig. 4D), which is

201 thought to be less acidic than the *mid*- and *trans*-cisternae.

202 Based on the previous observations, we believe that SidK-AL568 is an excellent probe to

203 detect V-ATPase, possibly superior to other reagents commonly used in the literature. Indeed,

204 when compared to a commercially available antibody raised against the same subunit to which

205 SidK-AL568 binds (V-ATPase subunit A), our probe yielded better results. The antibody chosen

206 for comparison (α-ATP6V1A) is widely used in the literature to document the localization of V-

207 ATPases, often as the basis to reach important functional conclusions (e.g. Ramirez et al.,

208 2019). When tested in HeLa cells (Figs. 4G and H), this antibody yielded a diffuse punctate

209 pattern reminiscent of that reported by Ramirez et al. (2019) for tumour cells and elsewhere for

210 a variety of other cells stained with other A subunit antibodies (Yajima et al., 2007; McGuire et

211 al., 2019; Michel et al., 2013). However, its co-localization with acidic compartments was poor:

212 the Manders' coefficient of the antibody with LAMP1 was M = 0.08 (compared to an M = 0.79

213 with SidK-AL568), while that with anti-TGN46, the *trans*-Golgi marker used, was M = 0.05

214 (compared to an M = 0.81 with SidK-AL568). Comparison of the α-ATP6V1A signal with that of

215 SidK-AL568 showed that most of the α-ATP6V1A staining was background, which was removed

216 by applying the unbiased Costes thresholding method prior to colocalization analysis (Costes et

217 al., 2004); see Materials and Methods); this was not the case for SidK-AL568 staining (Fig. S1).

218 We therefore suggest that SidK-AL568 is a more specific, preferable probe.

219

220 **Assessment of V-ATPase acquisition by maturing phagosomes**

221   The phagosomes formed by cells of the innate immune system, such as macrophages, are

222   specialized compartments with microbicidal and degradative functions. The lumen of nascent

223   phagosomes is near-neutral, but becomes gradually acidic as the compartment matures,

224   reaching a pH ≤ 5 (e.g. Fig. 5A). This acidification has been demonstrated to depend on the

225   activity of V-ATPases (Lukacs et al., 1990), which are nevertheless undetectable on the

226   macrophage plasma membrane that forms the initial phagosomal enclosure. The graded

227   acidification is thought to result from accumulation of V-ATPases complexes owing to fusion of

228   the nascent phagosome with early and late endosomes and, ultimately, with lysosomes.

229   Remarkably, to our knowledge, this purported mechanism has not been documented

230   experimentally. We therefore utilized the SidK-AL568 probe to detect V-ATPases during the

231   phagosomal maturation process, using murine macrophages (RAW264.7 cells) that had been

232   transfected with various membrane markers correlated to maturation state (Fig. 5B).

233   Like HeLa cells, resting RAW264.7 macrophages showed distinct vesicular staining with

234   SidK-AL568, as well as larger vacuoles that likely form by macropinocytosis, which is

235   constitutively active in these cells (Fig. 5C). Nascent phagosomes, enriched by arresting

236   phagocytosis shortly (2 min) after exposure to the target particles, were identified by the

237   persistence of plasmalemmal markers (e.g. PM-GFP). As expected, these nascent phagosomes

238   were essentially devoid of V-ATPases, although V-ATPase-rich organelles seemed to

239   accumulate in their immediate vicinity (Fig. 5D). In contrast, early phagosomes –which are

240   measurably acidic and were identified by the acquisition of Rab5 and PtdIns(3)P– showed

241   distinct acquisition of SidK-AL568 into discrete areas (Fig. 5E and F). Late

242   phagosomes/phagolysosomes, which were identified by possessing Rab7 or LAMP1, were even

243   more enriched with SidK-AL568 (Fig. 5G and H), consistent with their highly acidic pH.

244   Interestingly, a patchy localization of SidK-AL568 was noted at all stages of phagosome

245   maturation, suggesting that the recruitment of V-ATPases may occur at restricted sites, which

246   may have important implications for traffic and pH regulation.

247

The V-ATPase is heterogeneously distributed on the membrane of acidic organelles

249   The discontinuous pattern of SidK-AL568 on the late-phagosome membrane is reminiscent

250   of the spatial segregation of other membrane components that was observed previously and

251   associated with the formation of ER-phagosome contacts (Levin-Konigsberg et al., 2019).

252   These contacts are established, at least partly, by interaction of phagosomal ORP1L with the

253   ER resident proteins VapA and VapB (Rocha et al., 2009; Loewen and Levine, 2005). We

254   considered the possibility that the SidK-AL568 patches represented similar regions of V-ATPase

255   exclusion from ER contact sites. To assess this possibility, phagosomes of RAW264.7 cells that

256   had been transfected with ORP1L-GFP were stained with SidK-AL568. Following transfection

257   (Fig. 6A), ORP1L and the V-ATPase showed an inverse distribution, the latter accumulating in

258   regions where the former was depleted. This segregation could be quantified and is represented

259   as a ratio of SidK-568:ORP1L fluorescence in the rightmost panel of Fig. 6A. In contrast, SidK-

260   AL568 co-distributed with Arl8b (Fig. 6B), which was shown earlier to be excluded from ER

261   contact sites (Levin-Konigsberg et al., 2019). It was imperative to ensure that the apparent

262   depletion of V-ATPases from contact areas was not caused by limited access of SidK-AL568.

263   Accessibility was verified by immunostaining VapB alongside SidK-AL568 (Fig. 6C). As was the

264   case for ORP1L, the regions that were rich in VapB were comparatively depleted of SidK-

265   AL568. Because the antibody used to immunostain VapB is much larger (≈150 kDa) than SidK-

266   AL568 (≈35 kDa), exclusion of the V-ATPase ligand cannot account for the observed

267   segregation, which is an indication of the genuine existence of V-ATPase-enriched

268   microdomains.

269   The realization that unappreciated microdomains rich in V-ATPases exist in phagosomes

270   prompted us to ask whether similar subdomains exist in other organelles. To facilitate

271   visualization, we initially generated enlarged lysosomes using sucrose (Cohn and Ehrenreich,

272   1969; Bright et al., 1997; DeCourcy and Storrie, 1991; Swanson et al., 1986; Ferris et al., 1987)

273   in cells that had been transfected with ORPL1 (Fig. 7A) or Arl8b (Fig. 7B). As with late

274   phagosomes, V-ATPase (SidK-AL568) was depleted from membrane domains where ORPL1

275   was found, while coinciding with Arl8b.

276   In addition to visualizing V-ATPase microdomains in enlarged phagosome or sucrose-

277   enlarged lysosomes, the existence of comparatively long tubular lysosomes in macrophages

278   also enabled us to assess segregation in resting, unmodified cells. In RAW264.7 macrophages

279   (Fig. 7C) and human monocyte-derived macrophages (Fig. 7D), regions of late

280   endosome/lysosomes –identified by LAMP1– were preferentially enriched with V-ATPase. This

281   pattern could also be observed in some HeLa cells where the LAMP1-positive structures were

282   sufficiently large (Fig. 7E). In all cases, regions of V-ATPase exclusion from LAMP1-stained

283   areas were observed; in some instances SidK-AL568- stained structures appeared to bud off

284   from LAMP-positive tubular lysosomes. The observed segregation may be an indication of

285   selective delivery or removal of V-ATPases at varying stages of organellar maturation.

286

287   **Quantification of the number of V-ATPases per lysosome: evidence of heterogeneous**

288   **density that correlates with the subcellular localization of the organelles**

289   To date, estimates of the number of V-ATPase complexes in vesicular compartments

290   have been global approximations based on measurements made in pooled whole-cell

291   preparations (de Araujo et al., 2020; Takamori et al., 2006). In an effort to refine estimates and

292   provide topological information, we attempted to quantify the number of SidK-AL568 molecules

293   bound per organelle. This analysis required determination of the fraction of SidK molecules

294   labeled by the Alexa dye and the number of fluorophores attached per SidK-AL568 molecule,

295   followed by comparison of the single molecule fluorescence to the total fluorescence associated

296   with the organelle of interest. We determined that 96.7% of the molecules were labeled and

297   analysis of the photobleaching pattern of monodisperse SidK (Fig. 8A; see Materials and

298   Methods) indicated that 99% of these molecules had reacted with a single fluorophore (Fig. 8B).

299   We next determined the concentration of SidK-AL568 needed to saturate all the available

300   binding sites on lysosomes (Fig. 8C). With these parameters and conditions, the total

301   fluorescence associated with individual lysosomes was converted to a corresponding number of

302   V-ATPases, with the assumption that all three A subunits of every V-ATPase are accessible for

303   SidK-AL568 binding. In HeLa cells, where individual lysosomes can be delineated more readily

304   than in macrophages, the number of SidK-AL568 molecules associated per lysosome varied

305   (Fig. 8D), with an average of 4.42 ± 0.03 (mean ± SEM) SidK molecules per lysosome,

306   equivalent to 1.47 V-ATPase complexes per lysosome.

307   Previous research had shown that lysosomes are heterogeneous within a cell (Bright et al.,

308   1997, 2016; Butor et al., 1995; Cheng et al., 2018). Additionally, lysosomal pH can vary with

309   vesicle positioning, with peripheral lysosomes generally being more alkaline, and lysosomes

310   near the center of the cell being more acidic (Johnson et al., 2016; Webb et al., 2021). A simple

311   explanation for this finding could be that peripheral lysosomes have fewer V-ATPase complexes

312   than central lysosomes, although other mechanisms could also cause this effect (see

313   Introduction). To explore this phenomenon experimentally, lysosomes of HeLa cells were

314   identified with LAMP1 as a marker and their V-ATPase density quantified with SidK-AL568. The

315   resultant labeling with SidK-AL568 was more intense in juxtanuclear lysosomes than in more

316   peripheral lysosomes (Fig. 8E). This differential distribution was quantified and is represented

317   as a ratio of SidK-AL568:LAMP1 fluorescence (Fig. 8F). To more precisely assess whether the

318   number of V-ATPases per lysosome varies as a function of their subcellular localization, the

319   SidK-AL568 fluorescence of individual LAMP1-positive structures was analyzed relative to their

320   distance from the edge of the cell. Cell outlines were drawn and degraded inward by 4 μm

321   iteratively, to create concentric shells within each cell (Fig. 8G). Comparison of these

322   subgrouped LAMP1-positive vesicles confirmed the existence of a gradient of SidK-AL568 that

323   correlates with the distance of the lysosomes from the cell center. The most juxtanuclear

324   lysosomes bind approximately twice as many SidK-AL568 molecules as peripheral ones (Fig.

325   8H). This change in V-ATPase density corresponded to 2.1 V-ATPase complexes per lysosome

326   at >16 µm from the cell edge, compared to 1.1 lysosomal V-ATPases per lysosome for

327   lysosomes 0 to 4 µm from the cell edge. Interestingly, ≈18% of the lysosomes closest to the

328   nucleus showed more than the average number of V-ATPase complexes (2 to 6 per lysosome).

329   We conclude that the pH heterogeneity of lysosomes within individual cells can be explained, at

330   least in part, by differences in their V-ATPase density.

331

332   DISCUSSION

333   Despite its clear importance in the maintenance of organellar pH and tissue homeostasis,

334   the study of V-ATPases has been hampered by the lack of reagents to accurately localize and

335   quantify these complexes. To address this problem, we developed a detection tool based on

336   SidK, a *L. pneumophila* effector protein. SidK was an attractive detection tool for several

337   reasons. First, it was reported to bind to the V-ATPase A subunit with high specificity (Abbas et

338   al., 2020; Zhao et al., 2017; Xu et al., 2010) and affinity; SidK binds to the V-ATPase with a K_d≈

339   3.5 nM (Sharma and Wilkens, 2017), which is comparable to the affinity of many

340   immunoglobulins for their cognate antigens. Second, because the primary sequence of the V-

341   ATPase A subunit is highly conserved across Eukarya, a SidK-based reagent should be

342   applicable to a variety of model organisms. Indeed, we found SidK to interact equally with yeast

343   and mammalian cells. Finally, unlike other V-ATPase subunits, the A subunit exists as a single

344   isoform, so that the SidK reagent would be expected to bind V-ATPase wherever present in

345   organelles, cells, and tissues.

346   We first expressed the V-ATPase-binding region of SidK (amino acids 1 to 278) as a fusion

347   with GFP or mCherry. At modest expression levels, this construct enabled the detection of V-

348   ATPase-rich membranes. However, at higher expression levels the unbound (cytosolic) probe

349   obscured the intracellular organelles. This problem could be mitigated by leaching the cytosolic

350   excess out the cells by permeabilizing the plasmalemma with PLY, revealing the specifically-

14

351   bound constructs. However, when expressing SidK, a process that requires hours, we observed

352   a change in lysosomal positioning that we attributed to its inhibitory effect, as it mimicked the

353   effects of concanamycin A. Accordingly, we measured a ≈ 30% inhibition of the proton-pumping

354   rate in cells expressing SidK-mCherry. While our findings were not unexpected considering the

355   observations made earlier *in vitro* and in cells (Abbas et al., 2020; Zhao et al., 2017; Xu et al.,

356   2010; Johnson et al., 2016), they nonetheless underscored a limitation inherent to the use of

357   ectopically expressed SidK. Indeed, inhibition of V-ATPase and the resultant changes in luminal

358   pH can affect not only lysosome localization, but also the ability of the V-ATPase to interact with

359   other molecules (Maranda et al., 2001; Hurtado-Lorenzo et al., 2006; Hosokawa et al., 2013),

360   altering intracellular signaling (Balgi et al., 2011; Hu et al., 2016). In this context, it is noteworthy

361   that SidK-GFP/mCherry did not properly label acidic portions of the Golgi complex. This lack of

362   labeling could have resulted from obstruction caused by other molecules that associate with V-

363   ATPase in the Golgi, but not with those of the endocytic compartment.

364   To circumvent the problems associated with SidK expression, we utilized fluorescently-

365   conjugated recombinant SidK as an overlay staining reagent, followed by washing to remove

366   unbound probe. SidK-AL568 localized to punctate and cisternal structures in mammalian cells,

367   with little nonspecific background. The high signal-to-noise ratio, along with specific organellar

368   markers allowed us to clearly discern V-ATPase-positive organelles, primarily endo/lysosomes

369   and the *trans*-Golgi. This labeling was in sharp contrast to the staining we obtained using a

370   commercially available antibody to the A subunit and the conditions for its use described in the

371   literature (Ramirez et al., 2019), which yielded results similar to those reported by others using

372   other available antibodies (Yajima et al., 2007; McGuire et al., 2019; Michel et al., 2013). V-

373   ATPase complexes have been shown to interact with several accessory proteins involved in

374   endocytic sorting and signaling (Merkulova et al., 2015; Maxson and Grinstein, 2014;

375   Marshansky et al., 2014). These interacting proteins include sorting nexins SNX27, SNX10 and

376   SNX11 (Merkulova et al., 2015; Chen et al., 2012; Xu et al., 2020), and the Ragulator complex,

15

377   which controls mTOR activation during nutrient sensing (Zoncu et al., 2011). Additionally, the V-

378   ATPase is hypothesized to function as a sensor of luminal pH, that regulates endocytosis

379   through a pH-dependent interaction with ARNO, the guanine nucleotide exchange factor for Arf6

380   (Hosokawa et al., 2013; Maranda et al., 2001; Hurtado-Lorenzo et al., 2006). Recently, some

381   members of TLDc protein family have been found to interact with V-ATPase domains and

382   modulate V-ATPase activity or stability (Merkulova et al., 2015; Castroflorio et al., 2021). These

383   reports have relied on immunoprecipitation with available V-ATPase antibodies to study

384   interactions. However, use of the more specific SidK-AL568 probe could provide more sensitive

385   and/or specific measurements of interactions, as well as the ability to visualize novel

386   interactions by high-resolution microscopy. Of interest, the 34.6 kDa SidK$_{1-278}$ fragment we used

387   is considerably smaller than conventional primary antibodies (IgG ≈150 kDa), which are often

388   used in combination with an equally large secondary antibody. Our smaller probe is better

389   suited to access V-ATPases, and could therefore be advantageous for immunogold-labeling for

390   transmission electron microscopy, where the penetrance of bulky antibodies can limit detection.

391   The smaller size of SidK-AL568 compared to SidK-GFP/mCherry may also explain why the

392   former is better able to detect V-ATPase in the Golgi complex, although fixation and

393   permeabilization may have also facilitated its access.

394   The successful labeling of the acidic intracellular compartments emboldened us to utilize

395   the probe to monitor the dynamics of recruitment of the V-ATPase to a specialized vesicular

396   compartment, the phagosome. The progressive development of phagosomal acidification is well

397   established and was assumed, yet not proven, to be associated with increasing V-ATPase

398   density. We found that while the nascent phagosome is virtually devoid of V-ATPases, the

399   presence of the complex becomes evident in early (Rab5- and PtdIns(3)P-positive)

400   phagosomes, and their number increases further as they attain the phagolysosomal stage.

401   Therefore, the increasing acidity during maturation can be attributed, at least in part, to an

402   increase in V-ATPase density. This increase in density correlates well with the recent finding

16

403   that acidification of phagosomes to a pH < 6 during the transition between early and late

404   phagosome results in the dissociation of Vps34 class III phosphatidylinositol-3-kinase from

405   these organelles (Naufer et al., 2018). Therefore, V-ATPase recruitment to the phagosome

406   would be expected to control the cessation of PtdIns(3)P synthesis on these compartments,

407   which is necessary for transition to the late phagosome/phagolysosome stage (Vieira et al.,

408   2001; Naufer et al., 2018).

409   We also observed that V-ATPase was not homogeneously localized throughout the

410   membrane of the phagosome, and similar observations were made in enlarged and normal

411   lysosomes. The existence of specialized subdomains was recently reported in phagosomes,

412   where it was associated with the formation of contacts with the ER and the extension of tubular

413   structures (Levin-Konigsberg et al., 2019). In the endocytic system, similar microdomains have

414   been postulated to play roles in cargo sorting and receptor recycling through tubulation

415   (Wijdeven et al., 2016; Rocha et al., 2009), and are likely also involved in phagosome

416   resolution. Once internalized material has been degraded by acidic hydrolases, essential

417   phagosomal and lysosomal membrane proteins must be parsed and redistributed within the cell

418   for reutilization. The reformation of the lysosomal compartment by membrane-retrieval following

419   content condensation was predicted long ago (Bright et al., 1997, 2016; Mullock et al., 1998),

420   but the fate of specific components has not been well documented. In the case of the V-

421   ATPase, retrieval from maturing phagosomes was demonstrated in *Dictyostelium discoideum*

422   (Clarke et al., 2010), but to our knowledge has not been studied in mammalian cells. The

423   observed V-ATPase-rich domains may be a precursor to the formation of recycling vesicles or

424   tubules. In this regard, pH gradients have been recently observed in tubules formed by

425   macrophages (Suresh et al., 2020; Naufer et al., 2018). Taken together, these findings suggest

426   that proton-pumping microdomains may form on acidic organelles during the tubulation and

427   fission that accompany resolution.

17

428   The high signal-to-noise ratio provided by the SidK-AL568 probe and its defined labeling

429   stoichiometry enabled us to quantify the number of V-ATPase complexes per organelle.

430   Quantification relied on the use of saturating concentrations of the probe, a requirement that

431   was fulfilled by analyzing the concentration dependence of SidK-AL568 binding. We calculated

432   the number of V-ATPases per lysosome to range between 1 and 6, averaging ≈1.5. This

433   number is similar to estimates for synaptic vesicles, with one V-ATPase per vesicle (Takamori et

434   al., 2006). The paucity of pumps per organelle likely accounts for the difficulty encountered in

435   their detection and highlights the need for highly-specific probes. It is important to emphasize

436   that our estimates for the number of V-ATPases rely on the assumption that all three A subunits

437   of every pump are accessible to the probe. Because an increasing number of proteins are

438   appreciated to bind to the V-ATPase, steric hindrance may curtail the number of available

439   subunits, which would result in an underestimate of the number of pumps. Through these

440   experiments, we noted that the distribution of V-ATPases in association with LAMP1-positive

441   structures was not homogeneous throughout the cell: more SidK-AL568 bound to juxtanuclear

442   lysosomes, when compared to peripheral lysosomes. Shell analysis showed that the density of

443   SidK-AL568 increased with distance from the cell edge, with the most central lysosomes

444   containing up to 6 V-ATPases. These data are in line with recent reports showing that

445   juxtanuclear lysosomes are, on average, more acidic than the more peripheral ones (Johnson et

446   al., 2016; Webb et al., 2021).

447   While bearing in mind the caveats raised above regarding the assumption of unimpeded

448   access to all the A subunits, our estimates can be used to calculate the rate of pumping of

449   individual lysosomal V-ATPases *in situ*. Experiments like those in Fig. 2H indicated that addition

450   of concanamycin alkalinized the lysosomes at an initial rate of 0.198 ± 0.1 pH.min^{-1}. Because at

451   steady state the activity of the pumps must have matched the proton leak unmasked by

452   concanamycin, the measured rate can be used to estimate pump activity. Considering the

453   buffering power of the lysosomes, which we estimated to be 23.5 mM.pH^{-1} –measured by

18

454   pulsing with ammonium– we calculate a proton flux per lysosome volume of 9.50×10^{-2}

455    $mmol.min^{-1}.L^{-1}$. Assuming an approximate lysosomal volume of $2 \times 10^{-17}.L^{-1}$ (de Araujo et al.,

456   2020; Yordanov et al., 2019), this measurement is equivalent to a flux of 953 $H^{+}.sec^{-1}$ per

457   lysosome. As ten protons are pumped by the V-ATPase for every three ATPs hydrolyzed (Zhao

458   et al., 2015), the flux corresponds to approximately 191 molecules of ATP hydrolyzed per

459   lysosome per sec. Considering that there are 1 to 2 pumps on average per lysosome, the

460   calculated flux is within the same order as the V-ATPase activity measured previously in cell-

461   free systems in mammals (29.2 ATP per $V-ATPase.sec^{-1}$; Abbas et al., 2020) and yeast (from

462   3.7-300 ATP per $V-ATPase.sec^{-1}$; Vasanthakumar et al., 2019; Uchida et al., 1985; Sharma and

463   Wilkens, 2017; Kawasaki-Nishi, 2001). The rate estimated here in intact cells may differ from

464   some of the *in vitro* measurements due to the effect of regulatory factors and parameters, such

465   as availability of counterions, phosphorylation, membrane lipid composition, etc. that are not

466   encountered in cell-free enzyme assays.

467   In summary, we have introduced a new, powerful probe to visualize and quantify V-

468   ATPases in eukaryotic cells. This probe enabled us to assess the subcellular distribution of V-

469   ATPases and, in combination with ratiometric pH determinations, estimate the rate of flux for

470   individual lysosome-associated V-ATPase complexes in intact cells. These results reveal

471   heterogeneity in the lysosomal compartment that is a result of vesicle location dependent

472   differences in V-ATPase density. We also expect this probe to be a useful label for super-

473   resolution imaging and electron microscopy, and anticipate that SidK-AL568 and similar SidK-

474   derived probes will contribute not only to studies of V-ATPase complexes in cells, but to our

475   understanding of endocytic and secretory processes more generally.

476

477

478   MATERIALS AND METHODS

479   **Cell culture**

480   HeLa and RAW264.7 cells were obtained from and authenticated by the American Type

481   Culture Collection (ATCC). Both cell lines tested negative for mycoplasma contamination by

482   DAPI staining. HeLa cells were grown in DMEM containing L-glutamine and 10% heat-

483   inactivated fetal calf serum (FCS; MultiCell, Wisent) at 37°C under 5% CO_2. RAW264.7 cells

484   were grown in RPMI-1640 medium containing L-glutamine and 10% heat-inactivated FCS, at

485   37°C under 5% CO_2.

486   To obtain non-polarized human monocyte-derived macrophages (M0 hMDMs),

487   peripheral blood mononuclear cells (PBMCs) were isolated from the blood of healthy donors by

488   density-gradient separation with Lympholyte-H (Cedarlane). Human monocytes were then

489   separated by adherence and incubated in RPMI-1640 containing L-glutamine, 10% heat-

490   inactivated FCS, 100 $U.mL^{-1}$ penicillin, 100 $\mu g.mL^{-1}$ streptomycin, 250 $ng.mL^{-1}$ amphotericin B

491   and 25 $ng.mL^{-1}$ hM-CSF (PeproTech) for 5 to 7 days, at 37ºC under 5% CO_2, before

492   experimentation.

493

494   **Reagents**

495   Mammalian expression vectors were obtained from the following sources: pmCherry-N1

496   (Clontech) and pEGFP-N1 (Clontech), sec61b-GFP (Addgene; plasmid no. 121159), PM-GFP

497   (Teruel et al., 1999), Rab5A-GFP (Roberts et al., 2000), PX-GFP (Kanai et al., 2001), Rab7-

498   GFP (Bucci et al., 2000), LAMP1-GFP (Martinez et al., 2000), ORP1L-GFP (Rocha et al., 2009),

499   Arl8b-GFP (Johnson et al., 2016). V_Oa1-, V_Oa2-, and V_Oa3-GFP were the kind gift of Dr. Shuzo

500   Sugita (UHN, Toronto).

501   Primary antibodies were purchased from the following vendors: anti-human LAMP1

502   (Developmental Studies Hybridoma Bank; catalogue no. H4A3-s), anti-VapB (Sigma-Aldrich;

503   catalogue no. HPA013144), anti-TGN46 (Abcam; catalogue no. ab50595), anti-GM130 (BD

504   Transduction Laboratories; catalogue no. 610822), anti-V1A (Abnova; catalogue no.

505   H00000523-M02). Secondary antibodies conjugated with Alexa Fluor-405, -488, -555 or -647

506   were purchased from Jackson ImmunoResearch Labs.

507   Fluorescently-conjugated 10 kDa dextrans, Alexa Fluor-405 and Alexa Fluor-568 NHS

508   esters, and fluorescently conjugated phalloidin and streptavidin were purchased from Invitrogen.

509   Concanamycin A, nigericin, DAPI, propidium iodide and cresyl violet were from Sigma-Aldrich.

510   Sheep red blood cells (SRBC; 10% suspension) were from MP Biomedicals. Anti-sheep red

511   blood cell antibodies were from Cedarlane Laboratories. Paraformaldehyde (PFA; 16% wt/vol)

512   was from Electron Microscopy Sciences.

513

514   **SidK-GFP/mCherry plasmid construction**

515         $SidK_{1-278}$ was amplified by PCR using plasmid pSAB35 (Abbas et al., 2020) as a

516   template, with the following forward and reverse primers, respectively: 5´-

517   GAGGAGGAATTCATGTCTTTTATCAAGGTAGGTATAAAAATG-3´ and 5´-

518   GAGGAGGGATCCCCTTTGCTTAAAGCATTTAATTTTTCG-3´. The PCR product was digested

519   with EcoRI and BamHI (New England Biolabs), and ligated into pmCherry-N1 and pEGFP-N1

520   plasmids that had been digested with the same restriction enzymes.

521   For illustrative purposes, a model of yeast V-ATPase with SidK-GFP bound (Fig. 1B)

522   was generated from PDB accession no. 5VOX, 1GFL and 6O7T, using *UCSF ChimeraX*

523   (Goddard et al., 2018).

524

525   **Purification of $SidK_{1-278}$ protein**

526   To purify $SidK_{1-278}$-3×FLAG, *Escherichia coli* strain BL21 was transformed with pSAB35

527   (Abbas et al., 2020) and grown at 30°C with shaking in 1 L LB medium (BioShop) supplemented

528   with 50 mg.L^{-1} kanamycin. At an OD_{600} of 0.6-0.8, protein expression was induced with 1 mM

529   IPTG and cells grown overnight at 16°C. All subsequent steps were performed at 4°C. Cells

530   were harvested by centrifugation at 5,250 ×g, resuspended in 25 mL HisTrap Buffer (50 mM

531   Tris-HCl pH 7.4, 25 mM imidazole, and 300 mM NaCl) and lysed by sonication. The cell lysate

532   was centrifuged at 38,000 ×g and the supernatant was loaded onto a 5 mL HisTrap Ni-NTA

533   column (GE Healthcare). The column was washed with HisTrap Buffer and protein eluted with a

534   linear gradient of imidazole from 25 to 300 mM in HisTrap Buffer over 10 column volumes.

535   Fractions containing 6×his-SidK$_{1-278}$-3×FLAG were pooled, mixed with TEV protease,

536   and dialyzed against 2 L Dialysis Buffer (50 mM Tris-HCl pH 7.4 and 300 mM NaCl) with 1 mM

537   dithiothreitol (DTT) overnight. Cleaved protein was dialyzed against 2×1 L Dialysis Buffer to

538   remove imidazole and DTT and passed through a 5 mL HisTrap column. The column was

539   washed with HisTrap Buffer and the flowthrough and wash were collected, pooled, and

540   concentrated in a centrifugal concentrating device (EMD Millipore). To remove aggregated

541   protein, SidK$_{1-278}$-3×FLAG was further purified with a Superdex 200 10/300 Increase gel filtration

542   column (GE Healthcare) equilibrated with 50 mM Tris-HCl pH 7.4 and 150 mM NaCl. Fractions

543   containing protein were pooled, concentrated, flash-frozen in liquid N$_2$, and stored at -80°C.

544

545   **Purification of *Saccharomyces cerevisiae* V-ATPase using SidK**

546   *Saccharomyces cerevisiae* strain BJ2168 was grown in 11 L yeast extract peptone

547   dextrose medium (YPD; BioShop) in a Microferm fermenter (New Brunswick Scientific) at 30°C,

548   with aeration of 34 cubic feet per hour, and stirring at 300 rpm. Yeast were harvested after 18 h

549   (OD$_{660}$ = 4.5) by centrifugation at 4,000 xg for 15 min at 4°C. All subsequent steps were

550   performed at 4°C. Cell walls were broken by bead beating in lysis buffer (phosphate-buffered

551   saline, pH 7.4, 8% (w/v) sucrose, 2% (w/v) sorbitol, 2% (w/v) glucose, 5 mM ☐-aminocaproic

552   acid, 5 mM *p*-aminobenzoic acid, 5 mM EDTA, and 0.001% (w/v) PMSF). Cellular debris was

553   removed by centrifugation at 3,000 xg for 10 min and cell membranes were collected by

554   ultracentrifugation at 152,957 x*g* for 40 min. The membrane pellet was resuspended in 36 mL

555   lysis buffer, divided into 4 aliquots, flash-frozen in liquid N_2, and stored at -80°C. Two membrane

556   pellets (corresponding to half a fermenter growth) were thawed and solubilized with addition of

557   n-dodecyl-β-D-maltopyranoside (DDM, Anatrace) to 1% (w/v) final concentration, and DDM-

558   solubilized *S. cerevisiae* V-ATPase isolated with M2 Affinity agarose gel (Sigma-Aldrich) pre-

559   loaded with $SidK_{1-278}$-3×FLAG as described previously (Abbas et al., 2020). Protein purity was

560   confirmed by SDS-PAGE using 4–20% Mini-PROTEAN TGX protein Gels (BioRad).

561

Transient DNA Transfection

563   HeLa cells were plated at on 18 mm glass coverslips at a concentration of ≈$5×10^4$

564   cells.mL^{-1}, 16-24 hr prior to transfection. FuGENE 6 (Promega) transfection reagent was used

565   according to the manufacturer's instructions to transfect HeLa cells at a 3:1 ratio (using 1.5 µL

566   FuGENE 6 and 0.5 µg DNA per well). RAW264.7 cells were plated on 18 mm glass coverslips

567   at ≈$2×10^5$ cells.mL^{-1}, 16-24 hr prior to transfection. FuGENE HD (Promega) transfection reagent

568   was used to transfect RAW264.7 cells at a 3.5:1 ratio (using 1.75 µL FuGENE HD and 0.5 µg

569   DNA per well). In all cases, monolayers were used for experiments 16 hr after transfection.

570

Ratiometric fluorescence microscopy for the measurement of lysosomal pH, V-ATPase

activity and buffering power

573   HeLa cells were plated on 18 mm glass coverslips and incubated overnight with 250 µg.mL^{-1}

574   fluorescein isothiocyanate (FITC)-conjugated 10 kDa-dextran, which was then chased for 1 h in

575   complete medium prior to imaging to visualize lysosomes. Coverslips were then mounted in a

576   Chamlide magnetic chamber and incubated in HBSS medium for fluorescence-based pH

577   determinations.

578   Steady-state lysosomal pH was determined by exciting FITC-dextran labelled lysosomes

579   sequentially at 481±15 nm and 436± 20 nm, collecting emitted light at 520±35 nm. The

23

580   fluorescence intensity of FITC when excited at ≈490 nm is highly pH dependent and was used

581   to determine the pH of lysosomes. The fluorescence when excited at ≈440 nm is much less pH

582   dependent and was used to correct for potential photobleaching or focal changes during image

583   acquisition, the 490 nm/440 nm fluorescence ratio of FITC is utilized to determine pH values.

584   Multiple fields of cells were imaged, and the data processed with Volocity.

585   The 490 nm/440 nm fluorescence ratios were converted to pH by sequentially incubating

586   the cells for 5 min in isotonic K^+ solutions (143 mM KCl, 5 mM glucose, 1 mM $MgCl_2$, 1 mM

587     $CaCl_2$) of different pH (pH 4.5, buffered with 20 mM acetic acid, pH 5.5, 6.5, 7.5 solutions

588   buffered with 20 mM MES), containing 10 µM nigericin and 5 µM monensin. Background-

589   subtracted 490/440 nm fluorescence ratios were then plotted against pH, and the data fitted by

590   least squares were used to interpolate the lysosomal pH.

591   For V-ATPase activity determinations, HeLa cells were acutely treated with 500 nM

592   concanamycin A and images were acquired at 30 s intervals for 10 min. The time dependence

593   of the resulting pH changes was then plotted in GraphPad Prism 6, and the initial rates of

594   alkalinization (per cell) were determined within 2 min of addition of concanamycin A.

595   For the determination of buffering power, HeLa cells containing FITC-dextran loaded

596   lysosomes were challenged with 0.5 mM NH_4Cl and the resulting change in fluorescence

597   intensity (490 nm/440 nm) was measured immediately. The corresponding pH change,

598   calculated as above, was used to calculate the concentration of NH_4^+ formed inside the

599   lysosome, using the Henderson-Hasselbalch equation, and the buffering capacity estimated as

600     $\Delta[NH_4^+]_{lys}/\Delta pH_{lys}$.

601

602   **Lysosome labeling, cresyl violet staining and dissipation of organellar pH**

603   For identification of lysosomes, HeLa cells were incubated overnight with 100 µg.mL^{-1}

604   fluorescently-conjugated 10 kDa-dextran at the time of transient transfection, 16 to 24 hr prior to

605   experiments. The next day, monolayers were washed 3× with PBS and placed in HBSS medium

606   at 37⁰C for 1 hr to chase the dextran to lysosomes. Monolayers were then imaged live by

607   confocal microscopy.

608   For cresyl violet staining, HeLa cells, seeded on 18 mm glass coverslips at a

609   concentration of 1×10^5 cells.mL^{-1}, were labeled with fluorescent dextran as described above.

610   Monolayers were then incubated at 37⁰C with 1 μM cresyl violet in Hanks' Balanced Salt

611   Solution (HBSS; MultiCell, Wisent) for 5 min, washed 3 times and imaged live by confocal

612   microscopy. In some cases, organellar pH was dissipated prior to cresyl violet staining. To this

613   end the cells were treated for 30 min with 250 nM concanamycin A and 10 mM NH$_4$Cl in

614   HBSS. After this treatment, monolayers were stained with 1 μM cresyl violet and imaged live, as

615   above.

616

617   **Fluorescent labeling of SidK$_{1-278}$**

618   Prior to labeling, purified SidK$_{1-278}$-3×FLAG (see above; referred to in the text as SidK)

619   was buffer exchanged into PBS using a centrifugal concentrator (EMD Millipore). Following this,

620   SidK was directly labeled by conjugation with Alexa Fluor-568 NHS-ester (Invitrogen). A 10:1

621   dye:SidK molar ratio was prepared in 0.05 M borate buffer, vortexed, and incubated shaking at

622   500 rpm for 1 hr at room temperature. Labeled SidK (referred to as SidK-AL568) was then

623   dialyzed in 4× 1 L PBS, to remove unincorporated dye. One volume of 100% glycerol was

624   added to the SidK-AL568 for stability, and stored at 4°C.

625   The fraction of SidK labeled with Alexa Fluor-568 was determined using absorbance

626   spectroscopy on a Nanodrop 2000 instrument (Thermo Scientific). SidK and SidK-AL568 was

627   diluted to 0.1 mg.mL^{-1} in PBS. The A280 of SidK and its molecular weight (34,646 g.mol^{-1}) was

628   used to calculate its extinction coefficient (ε $SidK$ = 41,690 cm^{-1}.M^{-1}). Then, the A280 and A577

629   (λ_{max} of Alexa Fluor 568) of SidK-AL568 were measured and the degree of labeling (moles of

630   dye per mole of protein) for SidK-AL568 calculated, using the following two equations, along

631   with the ε *dye* value for Alexa Fluor 568 (91,300 cm^{-1}.M^{-1}) and the correction factor for the *A*280

632   contribution of Alexa Fluor-568 (*CF*280 = 0.46):

$$(1) \quad \text{protein concentration (M)} = \frac{[A280\text{-}(A577 \times CF280)] \times \text{dilution factor}}{\varepsilon\ SidK}$$

$$(2) \quad \text{moles dye per mole protein} = \frac{A577 \times \text{dilution factor}}{\varepsilon\ dye \times \text{protein concentration}}$$

633   The number of dye particles per SidK-AL568 molecule was determined by single-

634   molecule photobleaching imaging (Liesche et al., 2015). Briefly, a 10^6 dilution of SidK-AL568

635   was prepared and added to clean coverslips, creating a monodispersed sample. Monodispersed

636   SidK-AL568 was then imaged continuously by confocal microscopy at ≈ 5 frames.sec^{-1}, until

637   spot disappearance occurred through photobleaching. Time series images were analyzed using

638   Volocity v6.3 software (Quorum Technologies), and SidK-AL568 molecule fluorescence over

639   time plotted to generate traces where the number of steps required for SidK-AL568 spot

640   disappearance were counted. Each step corresponded to a single Alexa 568 dye molecule

641   conjugated to SidK. The average fluorescence value for *bona fide* single bleach step SidK-

642   AL568 was used to calculate the percent of SidK-AL568 in the monodispersed population with

643   1, 2, 3, or 4 or 5+ dye molecules per SidK.

644

Culturing of yeast and immunofluorescence of yeast spheroplasts

646   Wild type (*MATα ura3–52 leu2–3,112 his4–519 ade6)* and *vma1Δ (MATα ura3–52 leu2–*

647   *3,112 his4–519 ade6 vma1Δ::LEU2*) *S. cerevisiae* strains were kindly gifted by Dr. Morris

648   Manolson (University of Toronto). Yeast cultures were routinely grown at 30°C, with shaking, in

649   YPD medium (BD Biosciences).

650   For spheroplast preparation, overnight cultures were diluted 1:100 in YPD broth and

651   grown at 30°C for 2 hr. One mL of yeast culture was then fixed with 4% PFA for 30 min, while

652   shaking at room temperature. After washing cells 2✕ with 0.1 M KHPO$_4$ pH 6.5, yeast were

26

653   washed 1✕ in K-Sorb (1.2 M sorbitol in 0.1 M KPHO$_4$) and resuspended in 0.5 mL K-Sorb

654   containing 5 µL β-mercaptoethanol and 10 mg.mL^{-1} zymolyase 20T (MP Biomedicals). Cells

655   were shaken at room temperature for 30 min, and gently washed 2✕ with K-Sorb. After final

656   resuspension in 0.5 mL K-Sorb, 20 µL of spheroplast suspension was spread on a concanavalin

657   A-coated slide and allowed to adhere for 15 min at room temperature. Following this,

658   spheroplasts were permeabilized/blocked for 30 min in PBS 0.1% Tween-20 containing 5% BSA

659   and 5% skim milk. Samples were then incubated in the same buffer containing 1:200 SidK-

660   AL568 and 1 µg.mL^{-1} DAPI for 30 min at room temperature. After staining, slides were washed

661   3✕ with PBS and visualized by confocal microscopy.

662

663   **Immunofluorescence of mammalian cells**

664   After fixing in 3% PFA for 10 min at room temperature, cells were washed in PBS and

665   permeabilized/blocked in PBS containing 5% BSA and 0.1% Triton X-100 for 30 min at room

666   temperature. Samples were then incubated with primary staining reagents for 30 min at room

667   temperature. Primary antibody dilutions were: LAMP1 (1:50), VapB (1:100), TGN46 (1:100),

668   GM130 (1:100), V1A (1:100). For mitochondrial staining, fluorescently-conjugated streptavidin

669   was used at 1:100 dilution. SidK-AL568 was used at 1:100, 1:50 or 1:25 dilution, as indicated in

670   the text. Where indicated, a 5-fold excess of unlabeled SidK$_{1-278}$ was used in the

671   blocking/permeabilization step, to block SidK-AL568 binding sites prior to the addition of SidK-

672   AL568. After primary staining, monolayers were washed 3✕ with PBS, and samples incubated

673   30 min at room temperature with Alexa Fluor-conjugated secondary antibodies at a 1:1000

674   dilution. Where indicated, 1:1000 fluorescent phalloidin or 1µg.mL^{-1} DAPI was added together

675   with the secondary antibodies. Samples were washed 3✕ with PBS and viewed by confocal

676   microscopy in PBS.

677

678   **Phagosome and sucrosome analyses**

679   For phagocytosis assays, RAW264.7 cells were plated at on 18 mm glass coverslips at a

680   concentration of 2×10^5 cells.mL^{-1} and grown for 16-24 hr. Cells were transfected as described

681   above with the constructs indicated in the text. The day of experiments, SRBCs were prepared

682   for use in phagocytosis. Briefly, 100 µL of SRBC suspension was washed with 3✕ with PBS and

683   labeled with Alexa Fluor-405 NHS ester for 20 min, shaking at room temperature. SRBC were

684   then opsonized with 2 µL of rabbit anti-SRBC IgG at 37°C for 1 h. Prepared SRBCs were

685   washed 3✕ with PBS and resuspended to a final volume of 1 mL in PBS. After 1:10 dilution in

686   PBS, 25 µL of this suspension was added to the RAW264.7 cells. Alternatively, FITC-labelled

687   zymosan was diluted to 10 mg.mL^{-1} in PBS and opsonized by incubation with human IgG (final

688   IgG concentration, 5 mg.mL^{-1}) for 30 min at room temperature. Prepared zymosan was then

689   washed 3✕ with PBS and resuspended to a final volume of 20 µL in PBS. 1 µL of this

690   suspension was added to RAW264.7 seeded onto coverslips. In all cases, phagocytosis was

691   synchronized by sedimenting particles onto the cells using centrifugation at 300 ✕g for 1 min.

692   After phagocytosis, monolayers were fixed in 3% PFA for 10 min at room temperature and

693   stored in PBS until used. FITC-zymosan phagocytosis, which was used to determine the rate of

694   acidification of the nascent phagosome, was imaged immediately after sedimentation of the

695   particles.

696   To generate sucrosomes, transfected RAW264.7 cells were incubated for 16 to 24 hr in

697   RPMI-1640 medium containing L-glutamine, 10% heat-inactivated FCS and 30 mM sucrose, at

698   37°C under 5% CO_2. The next day, cells were washed 3✕ with PBS, placed in RPMI-1640

699   medium containing L-glutamine and 10% heat-inactivated FCS, and used for experiments as

700   described in the text. After experiments, monolayers were fixed in 3% PFA for 10 min at room

701   temperature and stored in PBS.

702

703   **Quantitation of the number of SidK-AL568 per lysosome**

704   The average fluorescence value of monodispersed SidK-AL568 molecules was used to

705   estimate the number of SidK-AL568 monomers per lysosome in HeLa cells that had been co-

706   stained with SidK-AL568 and LAMP1. 1:25, 1:50 and 1:100 SidK-AL568 dilutions were

707   assessed to determine the conditions required for saturation of SidK-AL568 staining, needed to

708   estimate the maximum number of SidK-AL568 molecules bound per LAMP1$^+$ lysosome.

709

710   **Microscopy**

711   Confocal images were acquired using a spinning disk system (Quorum Technologies

712   Inc.). The instrument consists of a microscope (Axiovert 200M; Zeiss), scanning unit (CSU10;

713   Yokogawa Electric Corporation), electron-multiplied charge-coupled device camera (C9100-13;

714   Hamamatsu Photonics), five-line (405-, 443-, 491-, 561-, and 655-nm) laser module (Spectral

715   Applied Research), and filter wheel (MAC5000; Ludl) and is operated by Volocity v6.3. Images

716   were acquired using a 63×/1.4 NA oil objective (Zeiss), with an additional 1.5× magnifying lens

717   and the appropriate emission filter. For live experiments, cells were maintained at 37°C using an

718   environmental chamber (Live Cell Instruments).

719   Ratiometric fluorescence pH measurements were acquired on an epifluorescence

720   microscope (Axiovert 200M; Zeiss) running on Volocity v6.3, equipped with a camera (Flash

721   4.0v2; Hamamatsu), excitation lamp (X-Cite 120; EXFO Life Sciences Group), a 63x/1.4 NA oil

722   objective (Zeiss), the appropriate dichroic mirror (CFP/YFP; Chroma Technology), and filter

723   wheels containing the necessary filters for FITC ratiometric fluorescence determinations

724   (excitation at 481±15 nm or 436±20 nm, emission 520±35 nm). All experiments were performed

725   maintaining the temperature at 37°C with an environmental controller (Medical Systems

726   Corporation).

727

728   **Image analysis**

729   Image processing and analyses were performed using Volocity v6.3. Image

730   deconvolution was done on acquired Z-stacks within the Volocity Restoration module, using the

731   iterative restoration function. Calculated fluorochrome point spread functions were used to

732   deconvolve individual channels for 5-8 iterations, until a confidence limit of >90% was achieved.

733   For colocalization analyses, Volocity Colocalization module was used to calculate the positive

734   product of the differences of the mean channels (Li, 2004), which was then overlaid on merged

735   images for visualization. Alternatively, for some colocalization analyses, Manders' overlap

736   coefficients were calculated in Volocity, which describe the percent of various organelle markers

737   that colocalize with SidK-AL568 (referred to as M).

738   The Volocity Ratio function was used for SidK-AL568 ratio calculations. This divides

739   background-subtracted intensities of SidK-AL568 and lysosomal, sucrosomal or phagosomal

740   markers (as indicated in the text), to calculate the ratio of SidK-AL568 fluorescence to that of the

741   chosen organellar marker. The Ratio function generates a rainbow LUT ratio channel that is

742   applied as an overlay on merged images, with a scale representing ratio values from 0 to 2.

743

744   **General methodology and statistics**

745   Data calculations and normalizations were done using Microsoft Excel 2011 (Microsoft

746   Corporation) or GraphPad Prism v9 software (GraphPad Software, Inc.). Because experiments

747   were, for the most part, *in vitro* imaging determinations of individual cells, samples were

748   assigned to groups according to specific experimental treatments (control vs. experimental

749   group). The number of individual experiments and the number of determinations per experiment

750   were selected to attain an estimate of the variance compatible with the statistical tests used,

751   primarily student's *t* test. Each type of experiment was performed a minimum of three separate

752   times (biological replicates) and a minimum of ten individual event determinations (equivalent,

753   but not identical to technical replicates). Data was tested for normality, and appropriate testing

754   applied. No data was excluded as outliers. All statistics were calculated using GraphPad Prism

755   v9.

756

Data availability

757

758   Experimental datasets that support the findings of this study are available from the

759   corresponding authors upon reasonable request.

760

761   **Online supplemental material**

762   **Figure S1** shows the (**A**) SidK-AL568 or (**B**) α-V1A staining of HeLa cells before (left)

763   and after (right) the thresholding used in the colocalization analyses (Costes et al., 2004) of

764   Figure 4**C** and 4**H**, respectively.

767   FIGURE LEGENDS

768   **Figure 1. SidK interacts with the V-ATPase *in vitro* and when expressed in mammalian**

769   **cells. A.** SDS-PAGE of 3×FLAG SidK$_{1-278}$ to illustrate purity of the probe and its ability to allow

770   isolation of yeast V-ATPase by affinity chromatography. Bands corresponding to SidK$_{1-278}$ and to

771   individual subunits of V-ATPase are labeled. **B.** Model of the yeast V-ATPase with SidK$_{1-278}$-

772   GFP bound, generated from PDB accession numbers 5VOX, 1GFL, and 6O7T. **C.** Visualization

773   of SidK$_{high}$ cells. Lysosomes of HeLa cells were transfected with SidK-GFP (green) and loaded

774   with Alexa Fluor-647-labelled 10 kDa dextran (magenta). Side panels show the individual SidK

775   and 10 kDa dextran channels in the region denoted by the dotted square, at 2.2× magnification.

776   **D.** Visualization of SidK$_{low}$ cells (green) labeled for lysosomes as in **C**. Side panels show the

777   individual SidK and 10 kDa dextran channels denoted by the dotted square, at 2.0×

778   magnification. **E** and **F.** Lysosomes were identified by LAMP1 immunostain (magenta) after

779   expression of high levels of SidK-GFP (SidK$_{high}$; green). Prior to fixation and immunostaining,

780   cells were either left untreated (**E**) or permeabilized with pneumolysin (PLY) to remove excess

781   cytosolic SidK-GFP (**F**). Side panels show the individual SidK and LAMP1 channels. Here and

782   elsewhere, outlines of cells are indicated by dotted lines when required. Images in **C-F** are

783   extended focus compressions of confocal images representative of ≥ 30 fields from ≥ 3 separate

784   experiments of each type. All scale bars: 5 µm.

785

786   **Figure 2. Effect of SidK-fluorescent protein overexpression on the pH of acidic**

787   **compartments. A.** Localization of endogenous LAMP1 (green) in untreated control cells. **B.**

788   Localization of LAMP1 (green) in cells expressing SidK-mCherry (red). Side panels show the

789   individual SidK and LAMP1 channels in the area denoted by the dotted square, at 2.0×

790   magnification. Arrowheads mark sites of peripheral LAMP1 accumulation. **C.** Localization of

791   LAMP1 (green) in cells treated with 250 nM concanamycin A for 1 hr. Arrowheads mark sites of

792   peripheral LAMP1 accumulation. **D.** Retention of the acidotropic dye cresyl violet (magenta) in

32

793   cells expressing SidK-GFP (green), where lysosomes had been preloaded with Alexa Fluor-

794   647-conjugated 10 kDa dextran (blue). Side panels show the individual channels of the area

795   denoted by the dotted square, at 2.7× magnification. **E.** Cells expressing SidK-GFP (green) and

796   labeled for lysosomes (blue) were treated with 250 nM concanamycin A and 10 mM NH_4Cl for

797   30 min to neutralize luminal pH. After treatment, cells were incubated with cresyl violet as in **D**.

798   Side panels are 2.7× magnification. Images in **A-E** are extended focus images representative of

799   ≥ 30 fields from ≥ 3 separate experiments of each type. All scale bars: 5 μm. **F.** Lysosomal pH

800   was determined in $SidK^-$ and $SidK^+$ HeLa cells. The lysosomes of control or SidK-mCherry-

801   transfected HeLa cells were loaded overnight with FITC-10 kDa dextran. Lysosomal pH was

802   subsequently measured by ratiometric fluorescence microscopy as described in the Materials

803   and Methods. For each condition, 3 independent experiments were quantified, with ≥ 20 cells

804   per replicate. Data are means ± SEM. *p* value was calculated using unpaired, 2-tailed student's

805   t-test. **G.** Lysosomal V-ATPase activity was measured in control and SidK-mCherry-expressing

806   HeLa cells acutely treated with 500 nM concanamycin A. V-ATPase activity was determined

807   from the inverse rate of alkalization upon the addition of concanamycin A. See Materials and

808   Methods for further details. For each condition, three independent experiments were quantified,

809   with ≥ 10 cells per replicate. Data are means ± SEM. *p* value was calculated using unpaired, 2-

810   tailed student's t-test.

811

812   **Figure 3. SidK-AL568 specifically labels the V-ATPase. A.** HeLa cells were stained with

813   SidK-AL568 (red) as described in the Materials and Methods either directly (left) or after

814   incubation with a 5-fold excess of unlabeled SidK$_{1-278}$ (right). F-actin was labeled with

815   fluorescent phalloidin (blue). **B.** Spheroplasts of wild type or *vma1Δ S. cerevisiae* were prepared

816   and stained with SidK-AL568 (red) as detailed in Materials and Methods. Nuclei were labeled

817   with DAPI (cyan). Outlines of the spheroplasts, visualized by DIC, are indicated by dotted lines.

818   **C** and **D.** HeLa cells were transfected with V_Oa2- (**C**) or V_Oa3-GFP (**D**) constructs (green), and

33

819   stained using SidK-AL568 (magenta). Nuclei were labeled with DAPI (blue). Outlines of cells are

820   indicated by dotted lines. Side panels show the individual SidK-AL568 and V_Oa channels.

821   Colocalization between SidK-AL568 and the corresponding V_Oa subunit is shown in orange and

822   the calculated Manders' coefficient (M) between the a subunit and SidK-AL568 is indicated. **A-D**

823   are extended focus compressions of confocal images representative of ≥ 30 fields from ≥ 3

824   separate experiments of each type. All scale bars: 5 µm.

825

826   **Figure 4. Localization of the V-ATPase in mammalian cells using SidK-AL568.**

827   **A**. HeLa cells were stained with SidK-AL568 (red), as described in Materials and Methods.

828   Nuclei were labeled with DAPI (blue). Arrowheads mark peripheral, likely endocytic, vesicles

829   (open) and juxtanuclear vesicles and cisternae, likely including the Golgi compartment (closed).

830   **B-F.** V-ATPase in HeLa cells was labeled with SidK-AL568 (magenta) and co-stained for **B**:

831   LAMP1, **C:** *trans*-Golgi, **D:** *cis*-Golgi, **E:** ER, and **F:** mitochondria (green) as described in the

832   text. Nuclei were labeled with DAPI (blue). Side panels show the individual SidK-AL568 and

833   organelle channels in the area denoted by the dashed square, at 1.1, 0.9, 1.1, 1.7 and 1.5×

834   magnification, respectively. Outlines of cells are indicated by dotted lines. **G** and **H.** HeLa cells

835   were immunostained using a commercially available V_1A antibody (Abnova; catalogue no.

836   H00000523-M02; shown in magenta) in cells co-stained for LAMP1 (**G**) or *trans*-Golgi (**H**), in

837   green. Nuclei were labeled with DAPI (blue). Side panels show the individual α-V_1A and

838   organelle channels marked by the dotted square, at 1.1 and 1.4× magnification, respectively. **A-**

839   **H** are extended focus images representative of ≥ 30 fields from ≥ 3 separate experiments of

840   each type. Outlines of cells are indicated by dotted lines. Colocalization and Manders'

841   coefficients (M) between the organellar marker and V-ATPase probe are shown in orange. All

842   scale bars: 5 µm.

843

844   **Figure 5. The acidification of macrophage phagosomes parallels the recruitment of the V-**

845   **ATPase to the phagosomal membrane, as detected by SidK-AL568. A.** RAW264.7 cells

846   were incubated with IgG-opsonized FITC-zymosan, which were sedimented by centrifugation

847   onto the coverslip to initiate phagocytosis. Phagosomal pH changes were determined by

848   ratiometric fluorescence microscopy, as described in the Materials and Methods. Time 0 marks

849   the point where phagosome acidification became evident. Data points (open circles) represent

850   the average of 2 independent experiments, with ≥ 10 cells per replicate. **B.** Schematic showing

851   the stages of phagosome engulfment and maturation, with associated membrane markers. **C.**V-

852   ATPase localization in resting RAW264.7 cells stained with SidK-AL568 (magenta). **D-H**.

853   RAW264.7 cells that had been transfected with the indicated phagosomal maturation markers

854   (green) were allowed to internalize IgG-opsonized SRBCs for various times before fixation. The

855   cells were then fixed, permeabilized, and stained with SidK-AL568 (magenta). **D.** Cells

856   expressing a plasma membrane (PM) marker, fixed 2 min after initiation of phagocytosis. **E.**

857   Cells expressing Rab5A, fixed 5 min after initiation of phagocytosis. **F.** Cells expressing a

858   PtdIns(3)P-specific probe, fixed 5 min after initiation of phagocytosis. **G.** Cells expressing Rab7

859   marker, fixed 30 min after initiation of phagocytosis. **H.** Cells immunostained for LAMP1, fixed

860   30 min after initiation of phagocytosis. **C-H** Are *XY* optical slices acquired near the middle of the

861   cell or phagosome, representative of ≥ 30 fields from ≥ 3 separate experiments of each type.

862   Outlines of cells are indicated by dotted lines. All scale bars: 5 μm.

863

864   **Figure 6. V-ATPase accumulates in subdomains along the phagosomal membrane and is**

865   **excluded from ER contact sites. A.** RAW264.7 cells that had been transfected with ORP1L-

866   GFP were allowed to internalize IgG-opsonized SRBCs and fixed after 60 min. Cells were

867   stained with SidK-AL568 (magenta) and visualized along with ORP1L (cyan). Individual SidK-

868   AL568 and ORP1L channels and the SidK-AL568:ORP1L fluorescence ratio ($Ratio_{SidK-}$

869   $_{AL568:ORP1L}$) are shown from left to right. Fluorescence ratio is pseudocolored in a rainbow LUT,

35

870   corresponding to ratio values from 0 to 2. **B.** RAW264.7 cells that had been transfected with

871   Arl8b-GFP were allowed to internalize IgG-opsonized SRBCs and fixed after 30 min. Cells were

872   stained with SidK-AL568 (magenta) and visualized along with Arl8b-GFP (cyan). Individual

873   channels and the pseudocolored fluorescence ratio are shown from left to right. **C.** Human M0

874   macrophages were allowed to internalize IgG-opsonized SRBCs and fixed after 30 min. Cells

875   were fixed, permeabilized and stained with SidK-AL568 (magenta) and immunostained for

876   endogenous VapB (cyan). Smaller panels show individual SidK-AL568, VapB and SidK-

877   AL568:VapB fluorescence ratio channels (*Ratio$_{SidK-AL568:VapB}$*) (top to bottom) for 3 individual

878   phagosomes (left to right) identified by the dotted squares, all at 1.8× magnification. **A-C** are

879   central *XY* optical slices optical slices acquired near the middle of the cell or phagosome

880   representative of ≥ 30 fields from ≥ 3 separate experiments of each type. Outlines of cells are

881   indicated by dotted lines. All scale bars: 5 µm.

882

883   **Figure 7. Lysosomes and lysosomal tubules in a variety of cell types show V-ATPase**

884   **subdomains. A.** RAW264.7 cells transfected with ORP1L-GFP were subjected to lysosome

885   enlargement by overnight treatment with 30 mM sucrose, as described in the Materials and

886   Methods. Cells were stained with SidK-AL568 (magenta) and the distribution of V-ATPase in

887   sucrosomes labeled with ORP1L (cyan) visualized. Side panels show the individual SidK-

888   AL568, ORP1L and colocalization channels (left to right). Colocalization and Manders'

889   coefficient between ORP1L and SidK-AL568 (M) are shown in orange. **B.** RAW264.7 cells

890   transfected with Arl8b-GFP were subjected to lysosome enlargement by overnight treatment

891   with 30 mM sucrose. Cells were stained with SidK-AL568 (magenta) and the distribution of V-

892   ATPase in sucrosomes labeled with Arl8b (cyan) visualized. Side panels show the individual

893   SidK-AL568, Arl8b and colocalization channels (left to right). Colocalization and Manders'

894   coefficients between Arl8b and SidK-AL568 (M) are shown in orange. **C-E** Localization of the V-

895   ATPase in tubular lysosomal structures in: **C.** RAW264.7 cells, **D.** human M0 macrophages, and

36

896 **E.** HeLa cells. Cells were stained using SidK-AL568 (magenta) and immunostained for

897 endogenous LAMP1 (cyan). Solid white arrowheads mark lysosomal regions that are SidK$^+$

898 LAMP1$^-$, while open arrowheads mark regions that are SidK$^-$ LAMP1$^+$. Side panels show

899 individual SidK-AL568, LAMP1 and colocalization channels (top to bottom). Colocalization and

900 Manders' coefficients between LAMP1 and SidK-AL568 (M) are shown in orange. **A-E** are *XY*

901 optical slices representative of ≥ 30 fields from ≥ 3 separate experiments of each type. All scale

902 bars: 5 µm.

903

904 **Figure 8. Estimation of the number of V-ATPases per lysosomal compartment. A.**

905 Photobleaching of monodisperse SidK-AL568. Representative intensity-time traces for a single

906 SidK-AL568 labeled with 1 (top) or 2 (bottom) Alexa Fluor 568 moieties. Loss of fluorescence

907 after complete photobleaching is shown by the dotted red lines. **B.** Histogram showing the

908 measured number of dye molecules per SidK-AL568 monomer determined analyzing > 5000

909 single molecule photobleaching traces. The number of SidK-AL568 molecules in each category

910 of the histogram is indicated above the bar. **C.** HeLa cells were stained with SidK-AL568 at

911 varying concentrations (shown in absolute concentration and as dilution). Lysosomal

912 fluorescence was plotted to determine the concentration of SidK-AL568 required to reach

913 maximal lysosome fluorescence, indicative of saturation of available binding sites. **D.** HeLa cells

914 were stained with SidK-AL568 using the near-saturation conditions determined in **C** (1:50). Total

915 fluorescence per lysosome was compared to the average fluorescence of a single molecule of

916 SidK-AL568 and is displayed; the average number of SidK-AL568 molecules bound per

917 lysosome is indicated by the horizontal line, as is the SE (whiskers). A total of 5715 lysosomes

918 from 2 independent experiments were quantified. **E.** Intracellular V-ATPase distribution among

919 lysosomes is heterogeneous. HeLa cells were stained with SidK-AL568 (magenta) using the

920 near-saturating conditions determined in **C** (1:50), and co-stained for LAMP1 (green). Side

921 panels show the individual LAMP1 (top), and SidK-AL568:LAMP1 colocalization channels

922   (bottom) for juxtanuclear (left) or peripheral (right) lysosomes in the areas denoted by the dotted

923   squares. Outlines of cells and lysosomes are indicated by dotted or solid lines, respectively. **F.**

924   SidK-AL568:LAMP1 fluorescence ratio ($Ratio_{SidK-AL568:LAMP1}$) corresponding to image in **E**. The

925   fluorescence ratio was pseudocolored in a rainbow LUT, representing ratio values from 0-2. **G.**

926   Shell analysis of SidK distribution as a function of distance from the cell outer edge. HeLa cells

927   were stained using SidK-AL568 and co-stained for LAMP1. Cell outlines were drawn and

928   degraded iteratively inward by 4 µm to create concentric shells (colored differentially) within

929   each cell that were used to subgroup LAMP1+ lysosomes for subsequent analysis. **H.** For each

930   shell, total fluorescence per lysosome was compared to the average fluorescence of a single

931   molecule of SidK-AL568, and the average number of SidK-AL568 molecules bound per

932   lysosome calculated, as a function of distance from the cell outer edge. Data are means ± SEM

933   of 2 independent experiments with ≥ 5 cells per replicate. N = 791, 1112, 1203, 1275 and 1334

934   lysosomes analyzed for shells 0-4, 4-8, 8-12, 12-16, and >16 µm from the cell edge,

935   respectively. Images in **E-G** are extended focus compressions of confocal images

936   representative of ≥ 10 fields from ≥ 2 separate experiments of each type. All scale bars: 5 µm.

937

938   SUPPLEMENTAL FIGURE LEGEND

939   **Figure S1. Demonstration of the Costes thresholding method used prior to colocalization**

940   **analyses.** HeLa cells were stained with (**A**) SidK-AL568 (magenta) or (**B**) α-V$_1$A (magenta), as

941   described in Materials and Methods. For both **A** and **B**, left panel shows staining before Costes

942   thresholding, while the right panel shows the same channel after thresholding. Outlines of cells

943   are indicated by dotted lines. Scale bars: 5 µm. Images in **A** and **B** correspond to Figure 4C and

944   4H, respectively.
