29 **Abstract**

30 Nuclear clearance of the DNA/RNA-binding protein TDP-43 is a pathologic hallmark of amyotrophic lateral

31 sclerosis and frontotemporal dementia that remains unexplained. Moreover, our current understanding of

32 TDP-43 nucleocytoplasmic shuttling does not fully explain the predominantly nuclear localization of TDP-43

33 in healthy cells. Here, we used permeabilized and live-cell models to investigate TDP-43 nuclear export

34 and the role of RNA in TDP-43 localization. We show that TDP-43 nuclear efflux occurs in low-ATP

35 conditions and independent of active mRNA export, consistent with export by passive diffusion through

36 nuclear pore channels. TDP-43 nuclear residence requires binding to GU-rich nuclear intronic pre-mRNAs,

37 based on the induction of TDP-43 nuclear efflux by RNase and GU-rich oligomers and TDP-43 nuclear

38 retention conferred by pre-mRNA splicing inhibitors. Mutation of TDP-43 RNA recognition motifs disrupts

39 TDP-43 nuclear accumulation and abolishes transcriptional blockade-induced TDP-43 nuclear efflux,

40 demonstrating strict dependence of TDP-43 nuclear localization on RNA binding. Thus, the nuclear

41 abundance of GU-rich intronic pre-mRNAs, as dictated by the balance of transcription and pre-mRNA

42 processing, regulates TDP-43 nuclear sequestration and availability for passive nuclear export.

Introduction

Transactive response DNA binding protein 43 kD (TDP-43) is an essential DNA/RNA-binding protein that

plays a major role in RNA processing and stability (reviewed in Prasad et al., 2019; François-Moutal et al,

2019). Loss of nuclear TDP-43 expression and accumulation of cytoplasmic aggregates is a pathologic

hallmark of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD) (Neumann *et al*, 2006;

Arai *et al*, 2006), where approximately 97% and 45% of cases show TDP-43 pathology at autopsy,

respectively (reviewed in Ling et al., 2013). Substantial evidence links TDP-43 disruption to the

pathogenesis of ALS and FTD, via loss of nuclear splicing regulation (Polymenidou *et al*, 2011; Tollervey *et

al*, 2011; Ling *et al*, 2015) and the toxic effects of cytoplasmic aggregates (reviewed in Vanden Broeck et

al., 2014; Prasad et al, 2019). Mutations in TDP-43 have been identified in families with inherited ALS

(Kabashi *et al*, 2008; Sreedharan *et al*, 2008; Deerlin *et al*, 2008; Gitcho *et al*, 2008) and FTD (Borroni *et

al*, 2009; Kovacs *et al*, 2009) and cause neurodegeneration in disease models (reviewed in Buratti, 2015),

supporting a role for TDP-43 disruption in the evolution of disease. Remarkably, the vast majority of ALS

and FTD cases involving TDP-43 cytoplasmic mislocalization are not associated with TDP-43 mutations,

indicating that diverse genetic, environmental, or age-related causes, possibly all involved in the same

underlying process, drive the nuclear clearance of TDP-43 in disease. However, the factor(s) responsible

for TDP-43 nuclear accumulation in healthy cells and mislocalization in ALS/FTD remain unclear.

TDP-43 is a member of the heterogenous ribonucleoprotein (hnRNP) family of RNA binding proteins

(RBPs) that contains an N-terminal bipartite nuclear localization signal (NLS), two RNA recognition mofits

(RRM1 and RRM2), and an intrinsically disordered C-terminal domain (reviewed in François-Moutal et al,

2019). RNA crosslinking and immunoprecipitation (CLIP-seq) studies show that TDP-43 preferentially binds

GU-rich RNA motifs, particularly within introns (Polymenidou *et al*, 2011; Tollervey *et al*, 2011), consistent

with its essential role in regulating alternative splicing and repression of cryptic exons (Ling *et al*, 2015).

Like many hnRNPs, TDP-43 continuously shuttles between the nucleus and cytoplasm (Ayala *et al*, 2008).

Ran-regulated active TDP-43 nuclear import occurs via binding of its NLS to importins α and β (Ayala *et al*,

2008; Nishimura *et al*, 2010). A modest degree of passive nuclear import also likely occurs based on size

and the low level of persistent nuclear entry seen in cells expressing TDP-43-ΔNLS (Ayala *et al*, 2008;

85   Winton *et al*, 2008). TDP-43 nuclear export was initially thought to occur via the exportin-1 (XPO1) receptor

86   and a putative nuclear export signal (NES) in RRM2 (Winton *et al*, 2008). However, several groups recently

87   showed that NES deletions do not disrupt TDP-43 export, nor does XPO1 knockdown or inhibition by

88   selective inhibitors of nuclear export (Ederle *et al*, 2018; Pinarbasi *et al*, 2018; Archbold *et al*, 2018).

89   Adding 54-119 kD tags to TDP-43 strongly slowed its export, as would be expected for a passive export

90   mechanism rather than an energy-dependent, active process (Pinarbasi *et al*, 2018; Ederle *et al*, 2018).

91   Meanwhile, transcriptional blockade promotes TDP-43 nuclear efflux (Ayala *et al*, 2008; Ederle *et al*, 2018),

92   as does overexpression of the mRNA export receptor NXF1 (Archbold *et al*, 2018), suggesting a role for

93   nuclear RNA in mediating TDP-43 nuclear localization and raising the possibility of TDP-43 co-export with

94   mRNA, perhaps via the TREX (TRanscription/EXport) pathway (discussed in Ederle & Dormann, 2017).

95

96   Here, we aimed to elucidate the mechanism of TDP-43 nuclear export and test the hypothesis that TDP-43

97   nuclear residence depends on its preferential binding to nuclear RNAs. Consistent with this idea, we found

98   that RNase-mediated nuclear RNA degradation in permeabilized cells markedly disrupted TDP-43 nuclear

99   sequestration, allowing TDP-43 to diffuse from the nucleus in low-ATP conditions. Moreover, in

100   permeabilized and live cell assays, introduction of GU-rich oligomers induced TDP-43 exit from the

101   nucleus, likely by competitive dissociation from endogenous nuclear RNAs. Inhibition of pre-mRNA splicing

102   caused dose-dependent TDP-43 nuclear accumulation and prevented its nuclear export upon

103   transcriptional blockade, further supporting the notion that nuclear accumulation of TDP-43 depends on its

104   association with pre-mRNAs. Taken together, our results indicate that binding to GU-rich intronic pre-

105   mRNAs retains TDP-43 within nuclei and dictates its availability for passive diffusion from the nucleus.

106

107   **Results**

108   **NVP-2-induced RNA Pol II inhibition promotes rapid TDP-43 nuclear export**

109   Actinomycin D, a DNA-intercalating agent and pan-transcriptional inhibitor, has been shown to induce the

110   nuclear efflux of a subset of nuclear RNA-binding proteins (RBPs) including hnRNPA1 (Piñol-Roma &

111   Dreyfuss, 1992), SR proteins (Cáceres *et al*, 1998), and TDP-43 (Ayala *et al*, 2008; Ederle *et al*, 2018). To

112   confirm that TDP-43 nuclear accumulation is sensitive to inhibition of mRNA synthesis and avoid the

113 possible pleiotropic effects of DNA intercalation, we treated HeLa cells with NVP-2, an inhibitor of CDK9-

114 dependent RNA Polymerase II activation (Olson *et al*, 2018) and monitored TDP-43 localization by

115 immunostaining (**Fig 1A-C**). RNA synthesis was analyzed in parallel via a brief pulse of 5-ethynyl-uridine

116 (5-EU) prior to fixation, to facilitate 'click-chemistry' labeling of newly transcribed RNAs (Jao & Salic, 2008).

117 Cells were imaged with an automated high-content spinning disc confocal microscope, and a translocation

118 algorithm was used to quantify the background-corrected fluorescence intensity in the nuclear and

119 cytoplasmic compartments (Hayes *et al*, 2020). Like actinomycin D **(Suppl fig 1A-C)**, NVP-2 caused

120 progressive, dose-dependent inhibition of RNA synthesis (**Fig 1A-B**), sparing RNA puncta within nucleoli

121 resulting from RNA polymerase I-dependent ribosomal RNA synthesis (**Fig 1A** arrows) (Sharifi & Bierhoff,

122 2018). In parallel, there was progressive TDP-43 nuclear efflux, as measured by a decrease in the nuclear

123 to cytoplasmic (N/C) ratio (**Fig 1A,C**). Importantly, the drop in the TDP-43 N/C ratio induced by both NVP-2

124 and actinomycin D corresponded to a decrease in nuclear immunofluorescence and an increase in

125 cytoplasmic immunofluorescence (**Suppl fig 1D-E**), consistent with TDP-43 translocation from the nucleus

126 to the cytoplasm. NVP-2 and actinomycin D treatment of mouse primary cortical neurons also induced

127 time- and dose-dependent transcriptional inhibition and TDP-43 nuclear efflux (**suppl fig 1F-J**).

128

129 Next, we compared the effect of NVP-2 on the localization of TDP-43 versus a panel of other RBPs,

130 including hnRNPs, RNA export proteins, members of the exon-junction complex, and splicing-associated

131 proteins (**Fig 1D and Suppl fig 2A-B**). Cells were treated with NVP-2 for up to 6 h, fixed, and RBP

132 localization was analyzed by immunofluorescence and automated high-content analysis. RBP responses

133 were diverse, including rapid nuclear efflux (TDP-43, HuR), slow nuclear efflux (FUS, hnRNPA1), and no

134 change (Matrin-3). DDX19b, an ATP-dependent RNA helicase in the mRNA export pathway that is tethered

135 to the NPC (Napetschnig *et al*, 2009; Hodge *et al*, 2011) was unchanged, serving as an internal control for

136 nuclear stability. hnRNPC, a resident nuclear hnRNP that does not exhibit N/C shuttling (Piñol-Roma &

137 Dreyfuss, 1992; Ederle *et al*, 2018) showed nuclear accumulation. Interestingly, TDP-43 was among the

138 most highly responsive RBPs to transcriptional blockade, suggesting strict dependence on nascent nuclear

139 RNA levels.

140

TDP-43 exits the nucleus by passive diffusion

Recent studies showed that TDP-43 nuclear export is independent of the XPO1 nuclear export pathway (Archbold *et al*, 2018; Pinarbasi *et al*, 2018; Ederle *et al*, 2018) and may passively leave the nucleus in a size-limited manner (Pinarbasi *et al*, 2018; Ederle *et al*, 2018). In support of this, we found that the addition of a relatively small 27-kD YFP tag markedly inhibited NVP-2-induced TDP-43 nuclear efflux (**Suppl fig 1K)**. However, the mechanism of passive versus active TDP-43 export across the NPC remains to be confirmed. Permeabilized cell assays have been widely used to study nucleocytoplasmic transport, facilitating investigations of transport mechanisms in isolation from other cellular processes and permitting a broad range of experimental perturbations (Adam *et al*, 1990; Cassany & Gerace, 2009). Most commonly, digitonin is used to selectively perforate the plasma membrane (Colbeau *et al*, 1971; Adam *et al*, 1990), releasing the cytoplasm and leaving the nuclear membrane and NPCs intact and able to perform either passive or energy-dependent bidirectional transport (Hayes *et al*, 2020). Here, we developed an assay for the passive nuclear export of endogenous TDP-43 in digitonin-permeabilized HeLa cells (**Fig 2A**). Post-permeabilization, cells were incubated in energy-free buffer and fixed at regular intervals to analyze the localization of TDP-43 by immunofluorescence. Nuclear envelope and NPC integrity was monitored by verifying that nuclei restrict the entry of a 70 kD fluorescent dextran (**Suppl fig 3A**), since the permeability barrier of the NPC increasingly excludes cargoes above 30-60 kD (Mohr *et al*, 2009; Timney *et al*, 2016). Using a luciferase-based reporter assay, we analyzed ATP levels following permeabilization and found that the total ATP concentration drops by ~97% immediately after digitonin treatment, compared to intact HeLa cells (**Suppl fig 3B**), confirming low ATP levels in the permeabilized cell system.

Next, we identified conditions permissive of TDP-43 nuclear export. Upon plasma membrane permeabilization and maintenance in buffer, with no added transport receptors or ATP, we saw a progressive decrease in nuclear TDP-43 immunofluorescence, to about 50% after 1 h, in cells heated to a physiological temperature at 37°C (**Fig. 2B-C**). However, there was only minimal change in nuclear TDP-43 over an identical time period when cells were permeabilized and kept at 4°C. These results indicate that, while TDP-43 can passively leave the nucleus in low-ATP conditions at 37°C, temperature-sensitive mechanism(s) hinder TDP-43 nuclear exit at 4°C beyond the expected ~linear reduction of free diffusion

169   with reduced temperature (Soh *et al*, 2010). To further test the passive nature of the observed export, we

170   added 1,6-hexanediol, an aliphatic alcohol that reversibly disrupts the phenylalanine-glycine (FG)-

171   permeability barrier lining the central channel of the NPC (Ribbeck & Görlich, 2002). 1,6-hexanediol caused

172   a marked, dose-dependent acceleration of TDP-43 nuclear efflux, suggesting that nuclear pore

173   permeability is a rate-limiting factor in TDP-43 nuclear export (**Fig. 2D–E**). Interestingly, 1,6-hexanediol

174   accelerated TDP-43 nuclear exit not only at 37°C but also at 4ºC, suggesting that the FG-repeat

175   permeability barrier is temperature-sensitive and contributes, at least in part, to the hindrance of TDP-43

176   passive export at 4ºC. Of note, 1,6-hexanediol also reversibly inhibits TDP-43 liquid-liquid phase separation

177   (LLPS) over the concentration range used (Gopal *et al*, 2017; Mann *et al*, 2019). Dissolution of nuclear

178   TDP-43 phase condensates could also contribute to the acceleration of TDP-43 nuclear export if LLPS

179   affects the availability of TDP-43 monomers for diffusion across the NPC, which remains to be investigated.

180   Consistent with lack of involvement of XPO1 in TDP-43 export, addition of the XPO1 inhibitor leptomycin B

181   (LMB, 100 nM) during the permeabilization, washing, and export phases did not alter TDP-43 nuclear efflux

182   (**Suppl fig 3C**). Next, we tested the effect of adding ATP and saw no change in the rate of nuclear export

183   at concentrations far exceeding those that support active nuclear transport in permeabilized cell systems

184   (Cassany & Gerace, 2009; Hayes *et al*, 2020, 2021) (**Suppl fig 3D**). To confirm that the data are not

185   confounded by TDP-43 import back into the nucleus, we tested the ability of our permeabilized cell system

186   to support active nuclear import. Although no import receptors or Ran cycle proteins were added to the

187   assay, residual importins do remain at NPCs upon cell permeabilization (Kapinos *et al*, 2017). Therefore,

188   we analyzed the capacity for nuclear import of Rango, a FRET sensor and direct importin β cargo (Kalab *et*

189   *al*, 2006; Hayes *et al*, 2020), and saw no import in our lysate-free conditions, with or without added ATP

190   (**Suppl fig 3E**). Our findings are therefore unlikely to be confounded by the nuclear re-entry of TDP-43.

191   Taken together, these data demonstrate that TDP-43 nuclear efflux in permeabilized cells is accelerated by

192   heat and 1,6-hexanediol, but not ATP, consistent with nuclear export by passive diffusion through NPC

193   channels.

194

195   **TDP-43 export is independent of NXF1-mediated mRNA export**

196   The observation that TDP-43 exits the nucleus in permeabilized cells under passive conditions, and its exit

197   is not accelerated by ATP, suggests that canonical, energy-requiring RNA export pathways are unlikely to

198   be required for TDP-43 nuclear export. This includes the exportin-family of receptors which rely on the

199   Ran-GTPase gradient (e.g. XPO1, XPOT, and XPO5), and the TREX bulk mRNA export pathway, which is

200   independent of Ran but requires the activity of ATP-dependent RNA helicases, including UAP56 and

201   DDX19b, for mRNP export complex assembly and disassembly (Okamura *et al*, 2015). In support of this,

202   individual siRNA knockdown of XPO1, XPO5, XPOT, the NXF1 mRNA export receptor, and AlyREF, a

203   TREX complex protein that participates in NXF1-recruitment, did not alter TDP-43 steady-state localization

204   (Archbold *et al*, 2018; Ederle *et al*, 2018). Similarly, TDP-43 RRM mutations did not prevent nuclear export

205   in the heterokaryon assay (Ederle *et al*, 2018). However, XPO1, XPO7, and NXF1 overexpression

206   promoted TDP-43 cytoplasmic redistribution (Archbold *et al*, 2018). Of note, NXF1 has also been identified

207   as a potential TDP-43 interacting protein (Freibaum *et al*, 2010).

208

209   To further exclude a role for the NXF1/TREX pathway in TDP-43 nuclear export, we utilized a DLD1 cell

210   line in which an auxin-inducible degron (AID) tag was introduced into the endogenous NXF1 locus via

211   CRISPR (Aksenova *et al*, 2020). TIR1 ligase, which drives ubiquitination of AID-tagged proteins upon

212   auxin-mediated recruitment, was separately integrated at the C-terminus of the nuclear protein RCC1 via a

213   self-cleavable P2A sequence. This enables rapid and complete degradation of the NXF1 protein within 1 h

214   of exposure to 0.5 mM auxin (**Fig 3A)**. Due to TIR1 leakage, DLD1-NXF1-AID cells showed mildly reduced

215   NXF1 expression even prior to auxin administration (**Fig 3A** asterisk). To examine the effect of NXF1

216   ablation on mRNA export, DLD1-wild-type and DLD1-NXF1-AID cells were treated with auxin for 0-8 h,

217   fixed, and poly(A)-RNA N/C localization was analyzed by fluorescence in situ hybridization (FISH) (**Fig 3B-**

218   **C**). DLD1-NXF1-AID cells showed an ~30% increase in the poly(A)-RNA N/C ratio even prior to auxin

219   administration (p<0.05 vs. DLD1-wild-type), consistent with the reduced NXF1 expression. Auxin induced

220   further, progressive accumulation of nuclear poly(A)-RNA to >300% of baseline by 8 h, consistent with the

221   inhibition of mRNA export (**Fig 3B-C**). To determine the effect of NXF1 ablation on transcriptional

222   blockade-induced TDP-43 nuclear export, cells were treated with auxin for 0-8 h, followed by a 2 h

223   incubation ± NVP-2 prior to fixation and TDP-43 immunostaining (**Fig 3D-E**). Interestingly, DLD1-NXF1-AID

224 cells showed an increased steady-state TDP-43 N/C ratio compared to DLD1-wild-type cells that increased

225 with auxin treatment, presumably due to TDP-43 binding to increased nuclear poly(A)-RNA (**Fig 3D**).

226 However, after adjusting for this increased steady-state N/C ratio, there was no delay in NVP-2-induced

227 TDP-43 nuclear export in DLD1-NXF1-AID cells until 8h, when subtle slowing was observed (**Fig 3E**).

228 These results suggest that inhibiting mRNA export promotes TDP-43 nuclear accumulation, but the NXF1

229 receptor itself does not mediate TDP-43 export across the NPC.

230

231 **TDP-43 nuclear localization depends on binding to GU-rich RNAs**

232 Since TDP-43 is primarily nuclear, despite its ability to diffuse through the NPC, we reasoned that TDP-43

233 localization must depend on intranuclear sequestration, perhaps binding to RNA given the rapid nuclear

234 efflux induced by transcriptional inhibition and nuclear accumulation conferred by mRNA export blockade.

235 To test this hypothesis, we added increasing concentrations of RNase A to permeabilized cells and

236 monitored the effect on TDP-43 nuclear localization (**Fig 4A-C**). In contrast to untreated controls, RNase

237 treatment caused rapid TDP-43 nuclear efflux over 30 minutes even at 4ºC, suggesting that RNA indeed

238 tethers TDP-43 within the nucleus. Interestingly, following RNase treatment, residual endogenous nuclear

239 TDP-43 formed puncta (**Fig 4B arrows**), as reported following nuclear RNase microinjection in living cells

240 (Maharana *et al*, 2018), and similar to the expression pattern of tagged, overexpression constructs of TDP-

241 43 RNA binding mutants (Ayala *et al*, 2008; Elden *et al*, 2010; Wang *et al*, 2020; Yu *et al*, 2020).

242 Furthermore, in addition to the temperature-induced changes in the NPC permeability barrier discussed

243 above (**Fig. 2D-E**), these results suggest that temperature-sensitive dissociation from RNAs contributes to

244 the drastically reduced passive TDP-43 nuclear exit at 4ºC versus 37°C. To assess nuclear integrity, we

245 also analyzed the effect of RNase on the nuclear localization of DDX19b (54 kD) and Nup50 (50 kD), two

246 proteins of similar size to TDP-43 that are localized to the NPC and nucleoplasm (**Suppl fig 4A**). The

247 nuclear intensity of both proteins was unaffected at 4ºC, and modestly diminished at 37ºC, but overall

248 remarkably stable compared to the rapid nuclear efflux observed for TDP-43. The observation of the critical

249 role of RNA in TDP-43 nuclear localization prompted us to test whether RNA degradation post-

250 permeailization contributes to the TDP-43 nuclear efflux we observed in our passive export assay (**Suppl**

251 **fig 4B**). We saw no difference in the rate of TDP-43 nuclear efflux in permeabilized cells kept at 37°C for

252   30 or 60 min, with or without RNasin, suggesting that RNA degradation does not contribute to the passive

253   export we observe. Nevertheless, RNasin was added to the transport buffer for all permeabilized cell

254   assays as a precautionary measure.

255

256   CLIP-seq studies demonstrate that TDP-43 preferentially binds repetitive GU-rich sequences, particularly

257   within introns (Polymenidou *et al*, 2011; Tollervey *et al*, 2011), and the RRM domains optimally recognize a

258   synthetic 'AUG12' (GUGUGAAUGAAU) motif (Lukavsky *et al*, 2013). To investigate the specificity of the

259   RNA-mediated nuclear tethering of TDP-43, we added synthetic RNA oligomers designed as 'decoys'

260   mimicking the preferred GU-rich binding sites to the permeabilized cell passive nuclear export system (**Fig**

261   **4D-G**). Following permeabilization, increasing concentrations of (GU)8, 'AUG12', or A16 oligomers were

262   introduced, and cells incubated at 4ºC for 30 min (**Fig 4D**). Both 'AUG12' and (GU)8 induced dose-

263   dependent nuclear efflux of TDP-43, presumably by competitive dissociation of TDP-43 from endogenous

264   nuclear RNAs, freeing TDP-43 to passively exit the nucleus. The A16 control oligomer had no effect.

265   Incubating permeabilized cells with (GU)8 at increasing temperatures (25°C and 37°C) markedly

266   accelerated (GU)8-induced TDP-43 export (**Fig 4E**), consistent with the expected temperature-dependency

267   of TDP-43 free diffusion, NPC permeability, and temperature-sensitive dissociation of TDP-43 from nuclear

268   RNAs.

269

270   Next, we evaluated the selectivity of the oligomer-induced nuclear efflux comparing different RNA motifs

271   and RBPs in the permeabilized cell system. (GU)8 induced nuclear efflux of TDP-43 but not three other

272   RBPs, including HuR which preferentially recognizes related U-rich motifs (**Fig 4F**) (e.g. UUGGUUU,

273   http://rbpmap.technion.ac.il/ (Paz *et al*, 2014; Silanes *et al*, 2004; Lebedeva *et al*, 2011)). Conversely,

274   polyU (U20) induced the nuclear efflux of HuR but not TDP-43 or other RBPs (**Fig 4G**). An oligomer based

275   on the U1 snRNP splice site sequence (CAAAGGUAAGUUGGA (Kondo *et al*, 2015)) selectively induced the

276   nuclear export of the U1 small nuclear ribonucleoprotein 70 kDa (U1-70K or snRNP70), with no significant effect

277   on the localization of TDP-43, hnRNPA2/B1, or PABPN1. C16 and A16 oligomers failed to induce nuclear

278   export of any RBPs tested, including those predicted to bind (i.e. hnRNPK and PABPN1, respectively (Choi *et*

279   *al*, 2009; Goss & Kleiman, 2013)). Thus, at least in the permeabilized cell system, these results show that

280 nuclear localization of a subset of RBPs, including TDP-43, depends on remarkably specific and selective

281 binding to their preferred binding motifs within nuclear RNAs.

282

283 Finally, we tested the ability of RNA oligomers to alter TDP-43 nuclear localization in live cells (**Fig 4H**).

284 HeLa cells were transfected with increasing concentrations of (GU)6 or A13 oligomers that were modified

285 by the addition of 2'-O-methyl groups and phosphorothioate bonds to prevent degradation by cellular

286 RNases. Cells were fixed 5 h after transfection for immunostaining and analysis. As in permeabilized cells,

287 (GU)6 but not A13 induced dose-dependent TDP-43 nuclear efflux (**Fig 4I**). Again, this was specific for

288 TDP-43 as there was no change in the N/C ratio of HuR, FUS, or hnRNPA2/B1 (**Fig 4J**). Together, these

289 findings confirm that in live cells, specific binding to endogenous GU-rich nuclear RNAs opposes the

290 tendency of TDP-43 to passively leave the nucleus.

291

292 **Inhibition of pre-mRNA splicing promotes TDP-43 nuclear accumulation**

293 Since GU-rich nuclear RNA binding appears critical for TDP-43 nuclear retention, we hypothesized that

294 TDP-43 nuclear accumulation relies on the abundance of GU-rich intronic sequences in newly-transcribed

295 pre-mRNAs prior to splicing and degradation of released introns. Since inhibition of pre-mRNA splicing

296 stalls intron excision and leads to nuclear accumulation of unspliced pre-mRNAs (Carvalho *et al*, 2017), we

297 used two splicing inhibitors, the Ginkgo biloba tree-derived bioflavinoid isoginkgetin (IGK) (O'Brien *et al*,

298 2008) and the bacterial macrolide pladienolide B (PLB) (Sato *et al*, 2014), to test whether nuclear intron

299 accumulation could reduce TDP-43 nuclear efflux. PLB binds and inhibits SF3B1 in the U2 snRNP in the

300 first step of spliceosome assembly (Kotake *et al*, 2007). The precise target of IGK has not yet been

301 identified, but it blocks the complex A to complex B transition during spliceosome assembly, downstream of

302 PLB (O'Brien *et al*, 2008). After a 4 h exposure, both IGK and PLB induced accumulation of introns as

303 determined by qRT-PCR analysis with primers targeting the exon/intron junction of selected housekeeping

304 genes, normalized to the expression of U6 snRNA, an unspliced transcript of RNA polymerase III (O'Brien

305 *et al*, 2008) **(Suppl fig 5).** Over the same time course, there was a dose-dependent increase in the steady-

306 state N/C ratio of TDP-43 (**Fig 5A-B, D-E**)**.** Remarkably, when cells were incubated for 4 h with IGK or

307 PLB, and NVP-2 was added to induce transcriptional blockade and TDP-43 nuclear efflux, both IGK and

308 PLB promoted TDP-43 nuclear retention, in a dose-dependent manner (**Fig 5C,F**). This effect was more

309 potent for IGK than PLB, albeit at higher doses (IGK IC_{50} = 62 μM, PLB IC_{50} = 6 nM). Together with the

310 observed effects of GU-rich oligomers in permeabilized and live cells, these data strongly suggest that

311 TDP-43 nuclear localization depends on the abundance of its nuclear intronic pre-mRNA binding sites.

312

313 **TDP-43 RRM domains confer RNA-dependent TDP-43 nuclear localization**

314 The RNA-binding properties of the TDP-43 RRM domains have been extensively characterized (Buratti &

315 Baralle, 2001; Lukavsky *et al*, 2013; Cohen *et al*, 2015; Flores *et al*, 2019). Although mutation or deletion of

316 the RRM domains does not abolish TDP-43 nuclear localization (Elden *et al*, 2010; Yu *et al*, 2020), these

317 observations arise from fluorescently tagged, high molecular weight TDP-43 constructs, which markedly

318 inhibits TDP-43 nuclear export (**Suppl fig 1K**; Ederle *et al*, 2018; Pinarbasi *et al*, 2018). However, Ayala

319 and colleagues previously generated TDP-43 RRM mutants with a small (~1 kD) FLAG tag and

320 demonstrated increased cytoplasmic localization by N/C fractionation and immunoblotting (Ayala *et al*,

321 2008). To further assess the role of the RRM domains for TDP-43 nuclear localization and export without

322 markedly increasing its molecular weight, we generated a series of constructs expressing V5-tagged wild-

323 type and RRM mutants of TDP-43 (**Fig 6A**), including mutations of phenylalanine residues (5F→L) and

324 acetylation sites (2K→Q) that are critical for RNA binding (Buratti & Baralle, 2001; Cohen *et al*, 2015), and

325 a complete RRM deletion (ΔRRM1-2). Constructs were transiently transfected into a stable HeLa cell line

326 largely depleted of TDP-43 by CRISPR (**Suppl fig 6A-B**) (generously provided by S. Ferguson (Roczniak-

327 Ferguson & Ferguson, 2019)) to avoid potential confounding effects of hetero-oligomerization with

328 endogenous TDP-43. High-content image analysis showed a significant drop in the steady-state N/C ratio

329 of all three RRM mutants, presumably exaggerated for ΔRRM1-2 due to its small size (29 kD) in

330 comparison to the point mutants (45 kD) (**Fig 6A-B**). In addition to reduced nuclear accumulation of the

331 RRM mutants, shuttling in response to NVP-2 was abolished. Next, we confirmed these findings with N/C

332 fractionation and immunoblotting (**Fig 6C-D**). The immunoblotting results corroborated our image-based

333 analyses, showing a marked reduction in the N/C ratio of TDP-43 in all three RRM mutants and no

334 response to NVP-2. Thus, TDP-43 RRM domains are required for nuclear TDP-43 localization and RNA-

335 regulated shuttling behavior.

336

337   Of note, coalescence of the V5-tagged RRM mutants into nuclear puncta was only rarely observed,

338   compared to widespread puncta observed in cells transfected with YFP-tagged TDP-43-5F→L (**Suppl fig**

339   **6C,F**) (Elden *et al*, 2010)**.** Since 27kD-YFP contains the same three residues (F223, L221, A206) known to

340   cause dimerization of GFP (Day & Davidson, 2009), the presumed nuclear phase separation behavior of

341   TDP-43 RRM mutants could be exacerbated by the size or dimerization activity of GFP-derived

342   fluorophores that can drive aberrant localization of tagged proteins in live cells (Snapp *et al*, 2003; Falcón-

343   Pérez *et al*, 2005). Indeed, we also saw a trend toward increased nuclear puncta formation by wild type

344   TDP-43-YFP compared to TDP-43-V5, though never to the extent of TDP-43-5FL-YFP (**Suppl fig 6F**).

345

346   **Role of HSP70 chaperone activity in nuclear/cytoplasmic localization of RNA-free TDP-43**

347   The HSP70 family of chaperones was recently shown to regulate the nuclear phase separation of RNA-free

348   TDP-43 into droplets or "anisosomes" (Yu *et al*, 2020). We wondered whether, in addition to NLS-mediated

349   nuclear import, HSP70 activity might therefore contribute to the nuclear localization of TDP-43 RRM

350   mutants. First, we confirmed that HSP70 inhibition strongly modifies fluorescent nuclear puncta in TDP-43

351   CRISPR KO cells transiently transfected with TDP-43-YFP or TDP-43-5FL-YFP (**Suppl fig 6C**). TDP-43-

352   5FL-YFP-expressing cells exhibited striking and widespread nuclear puncta, observed in 99.8% of cells vs.

353   35% of wild-type TDP-43-YFP-expressing cells (**Suppl fig 6F**). Consistent with the report of Yu and

354   colleagues, treatment with the HSP70 small molecule inhibitor VER 155008 (HSP70i, 50 µM) (Massey *et*

355   *al*, 2010; Yu *et al*, 2020) induced a steady decline in the number of TDP-43-5FL-YFP puncta per nucleus

356   (**Suppl fig 6D**), whereas no change was seen in TDP-43-YFP-expressing cells. Since the YFP tag alters

357   nuclear localization and export (**Suppl fig 1K**), next we verified that HSP70 also regulates nuclear puncta

358   formation using our V5-tagged RRM mutants (**Suppl fig 6E**). As shown in **Fig 6**, the V5-tagged proteins

359   formed far fewer nuclear puncta, observed in 9% of WT-V5, 17% of 2KQ-V5, 14% of 5FL-V5, and 13% of

360   ΔRRM1,2-V5-transfected cells (**Suppl fig 6F**). Puncta consisted of fine granules in 2KQ-V5 and 5FL-V5-

361   expressing cells and larger spherical/shelled structures in the ΔRRM1,2-V5-transfected cells (arrows in

362   **Suppl fig 6E**), and were more likely to be observed in higher-expressing cells across all constructs.

363   HSP70i induced a significant increase in the number of cells with nuclear puncta in both 2KQ-V5 and

364 ΔRRM1,2-V5-transfected cells, and a similar trend in 5FL-V5-transfected cells (**Suppl fig 6E-F**),

365 accompanied by increased mean puncta/nucleus and mean puncta area that was never observed in WT-

366 V5-expressing cells (**Suppl fig 6H**). Thus, while HSP70i induced the simplification of pre-existing nuclear

367 puncta in TDP43-5FL-YFP-expressing cells, it induced the formation of new and more numerous nuclear

368 puncta in cells expressing V5-RRM mutants with a smaller, dimerization-free tag. Given reduced antibody

369 penetration into densely-packed liquid spherical shells of larger anisosomes (Yu *et al*, 2020), it is possible

370 that the V5 immunofluorescence (IF) under-represents the amount of V5-TDP-43 residing in nuclear

371 puncta. However, N/C fractionation and immunoblotting (using denaturing conditions) showed a remarkably

372 similar distribution of V5-tagged TDP-43 to the results obtained with IF (**Fig 6**), indicating that only a small

373 fraction of the total V5-TDP-43 is enclosed in structures invisible by IF. Overall, HSP70i treatment is clearly

374 altering the nuclear distribution of V5-tagged RRM mutants (**Suppl fig 6**), confirming potent chaperone

375 activity in regulating the sub-nuclear localization of RNA-free TDP-43 in our model system.

376

377 Next, we analyzed the effect of HSP70i on the nuclear/cytoplasmic partitioning of TDP-43-V5 versus V5-

378 tagged RRM mutants at steady state and following NVP-2-induced transcriptional blockade (**Suppl fig 6I**).

379 Again, NVP-2 induced cytoplasmic shuttling of wild-type TDP-43-V5 and had no effect on the RRM

380 mutants. Interestingly, HSP70i did not further compromise the ability of RRM-mutant TDP-43 to remain in

381 the nucleus. Rather, HSP70i induced a modest (10-15%) increase in the TDP-43 N/C ratio of all three RRM

382 mutants that was not observed for wild-type TDP-43-V5. Thus, HSP70-dependent nuclear chaperone

383 activity appears to modestly favor the nuclear export of RNA-free TDP-43, by an unknown mechanism.

384 These data suggest that HSP70 chaperones do not contribute to the nuclear accumulation of RRM-mutant

385 TDP-43, which is most likely attributable to ongoing active and passive nuclear import.

386

387 **Discussion**

388 In this study, we investigated the mechanism of TDP-43 nuclear export and the regulatory role of RNA in

389 maintaining TDP-43 nuclear localization. In permeabilized cells, TDP-43 readily exited the nucleus in low-ATP

390 conditions, consistent with passive diffusion through NPCs. Acute depletion of NXF1 did not alter TDP-43

391 nuclear export in live cells, further excluding active TDP-43 co-export with mRNA. Three lines of evidence

392   indicate that binding to GU-rich nuclear RNAs sequesters TDP-43 in nuclei and controls its availability for

393   passive nuclear exit. (1) Degradation of nuclear RNAs by RNase treatment in permeabilized cells induced

394   rapid TDP-43 nuclear efflux, demonstrating that RNA is required for TDP-43 nuclear sequestration. (2) In

395   permeabilized and live cells, synthetic GU-rich oligomers induced nuclear TDP-43 exit, likely by competitive

396   displacement of TDP-43 from endogenous GU-rich nuclear RNAs. Moreover, splicing inhibitors promoted

397   TDP-43 nuclear accumulation and resistance to nuclear efflux upon transcriptional blockade, further

398   supporting the critical role of TDP-43 binding to intronic pre-mRNAs for maintenance of nuclear

399   localization. (3) Mutation or deletion of TDP-43 RRM domains strongly reduced TDP-43 nuclear enrichment

400   and abolished its RNA-regulated shuttling. Taken together, these findings support a model (**Fig 7**) in which

401   TDP-43 nuclear/cytoplasmic distribution results from a balance between active and passive TDP-43

402   nuclear import, nuclear sequestration by binding to GU-rich intronic pre-mRNAs, and passive nuclear

403   export. In this model, TDP-43 moves in and out of the nucleus via a reaction-diffusion-controlled

404   mechanism (Bastiaens *et al*, 2006; Soh *et al*, 2010) whereby transient formation of high molecular weight

405   TDP-43 complexes with nuclear pre-mRNAs ('reaction') locally sequesters TDP-43 within nuclei and

406   hinders availability of free TDP-43 for passive diffusion through NPC channels. Since inhibition of nuclear

407   RNA synthesis and competitive displacement with GU-RNA 'decoys' both induced net TDP-43 nuclear exit

408   in living cells, the active import rate of TDP-43 is clearly insufficient to balance passive export resulting

409   from loss of nuclear pre-mRNA binding sites. Either a drop in nuclear pre-mRNA binding sites or mutation

410   of the TDP-43 RRM domains steeply increases the nuclear abundance of TDP-43 that can passively

411   diffuse through NPCs, leading to (near) equilibration of TDP-43 between the nucleus and cytoplasm. By

412   maintaining the nuclear abundance of GU-rich intronic pre-mRNAs, the dynamic balance of transcription

413   and pre-mRNA processing may ultimately be the primary upstream factor determining TDP-43 nuclear

414   localization under physiological conditions.

415

416   **Transcriptional dependence of RBP nuclear enrichment**

417   Consistent with previous studies (Piñol-Roma & Dreyfuss, 1992; Cáceres *et al*, 1998; Ayala *et al*, 2008;

418   Ederle *et al*, 2018), we observed that transcriptional blockade altered the nuclear-cytoplasmic partitioning of

419   numerous RBPs, ranging from prominent accumulation in the cytoplasm (TDP-43 and HuR) to a nearly two-fold

420   nuclear increase (hnRNPC). Cytoplasmic-shifting RBPs included those with distinct RNA binding preferences,

421   such as TDP-43 (Polymenidou *et al*, 2011; Tollervey *et al*, 2011; Lukavsky *et al*, 2013), HuR (Lebedeva *et*

422   *al*, 2011), and hnRNPA1 (Bruun *et al*, 2016; Jain *et al*, 2017), as well as NXF1, which binds RNA in a

423   sequence-independent manner (Tuck & Tollervey, 2013; Baejen *et al*, 2014). Similarly, RBPs retained or

424   enriched in nuclei upon transcriptional inhibition included sequence-specific binders such as U2AF65 (Wu

425   *et al*, 1999; Zorio & Blumenthal, 1999; Merendino *et al*, 1999) and the DEAD-box helicase DDX19b which

426   has no sequence requirement (Lin *et al*, 2018). Thus, the diverse shuttling response of individual RBPs to

427   perturbation of transcription appears to be defined by RBP-specific protein-RNA and protein-protein

428   interactions rather than by a particular RNA motif.

429

430   Our mechanistic understanding of RNA synthesis-dependent N/C translocations of RBPs, including the factors

431   mediating RBP nuclear export or retention, remains incomplete (Nakielny & Dreyfuss, 1999). Several RBP-

432   specific functional domains have been identified to mediate nucleocytoplasmic shuttling, including the HuR

433   nucleocytoplasmic shuttling (HNS) domain (Fan & Steitz, 1998), the K nuclear shuttling (KNS) motif of

434   hnRNPK (Michael *et al*, 1997), the M9 signal required for transportin-mediated nuclear import and

435   transcriptional blockade-induced export of hnRNPA1 (Michael *et al*, 1995), the nuclear retention signal of

436   hnRNPC (Nakielny & Dreyfuss, 1996), and the SR domain of SF2 (SRSF1), which confers actinomycin D-

437   dependent shuttling to other proteins (Cáceres *et al*, 1998). Here, we demonstrate that the TDP-43 RRM1-

438   RRM2 domains mediate its transcriptional blockade-induced nuclear efflux and act as a nuclear retention

439   domain via binding nuclear RNAs. Interestingly, a recent study showed that the depletion of cytoplasmic RNAs,

440   via activation of the primarily cytoplasmic Xrn1 exonuclease-dependent mRNA decay, induced nuclear

441   translocation of many RBPs, including the cytoplasmic poly(A) binding protein PABPC (Gilbertson *et al*, 2018).

442   In a spatial inverse to our current model of TDP-43 shuttling, the findings of Gilbertson and colleagues suggest

443   that the cytoplasmic abundance of poly(A)-RNAs may be responsible for maintaining cytoplasmic PABPC

444   localization. Nucleocytoplasmic gradients of the preferred RNA binding motifs may therefore represent a

445   broadly-applicable model for regulating RBP localization, which warrants further investigation.

446

447   **Passive diffusion of TDP-43 across the NPC**

448   The FG permeability barrier of the NPC does not have a strict size cutoff; rather, diffusion of cargoes through

449   the NPC is increasingly restricted over the 30-60 kD range (Mohr *et al*, 2009; Timney *et al*, 2016). Thus, 43 kD

450   TDP-43 monomers are predicted to diffuse across the NPC with moderate efficiency. Indeed, we observed

451   TDP-43 nuclear efflux in permeabilized cells in low-ATP conditions, that was accelerated by NPC

452   permeabilization as expected for passive diffusion from the nucleus. These data corroborate predictions from

453   live-cell assays showing marked size-restriction of TDP-43 nuclear export, including slowed TDP-43-tdTomato

454   (+54 kD) export in the heterokaryon assay (Pinarbasi *et al*, 2018), lack of TDP-43-GCR$_2$-EGFP$_2$ (+119 kD)

455   cytoplasmic recovery in a dexamethasone-induced shuttling assay (Ederle *et al*, 2018), and failure of TDP-43-

456   YFP (+27 kD) nuclear efflux following transcriptional blockade (**Suppl fig 1K**). Delay in active nuclear import

457   has been demonstrated for very large cargos (Paci *et al*, 2020), and the rate of active mRNP export is

458   modestly size-dependent (Grünwald *et al*, 2011). However, the exquisite size-limitation of TDP-43 nuclear

459   export in live-cell assays is most consistent with passive diffusion from the nucleus, as our permeabilized cell

460   passive export assay confirms.

461

462   In addition to size, cargo surface properties also critically dictate NPC passage, including hydrophobic residues

463   which augment NPC transport (Frey *et al*, 2018). Besides the glycine-rich C-terminal IDR, hydrophobic patches

464   are present throughout the TDP-43 sequence (https://web.expasy.org/protscale/ (Gasteiger *et al*, 2005)),

465   including within the N-terminal domain, RRM1, and RRM2, but their roles in NPC passage are not known. A

466   recent study showed that intrinsically disordered proteins (up to ~63kDa) can passively transit through NPC

467   channels (Junod *et al*, 2020), suggesting that the disordered state of the TDP-43 C-terminal IDR could

468   potentially contribute to its passive nuclear exit. The potential role of TDP-43 hydrophobic and disordered

469   regions for passive translocation through NPC channels remains to be examined.

470

471   **Nuclear–cytoplasmic GU-rich RNA gradients and TDP-43 shuttling**

472   CLIP-seq studies have shown that TDP-43 preferably binds to long stretches of GU-rich intronic pre-mRNA

473   sequences present in about 30% of genes (Polymenidou *et al*, 2011; Tollervey *et al*, 2011). Introns are in

474   average much longer than exons in the predicted pre-mRNAs of human genes (7.5 kB vs 320 B (Lee & Rio,

475   2015)), and some are retained in exported mRNAs due to alternative splicing or incomplete debranching, and

476 detectable in the cytoplasm as stable intron lariats (Talhouarne & Gall, 2018; Saini *et al*, 2019). However, a

477 substantial proportion of nuclear intronic sequences, whether still contained in pre-mRNAs or excised, are likely

478 short-lived, due to the tight coupling of transcription with pre-mRNA splicing, pre-mRNA quality surveillance, and

479 rapid degradation via the nuclear exosome (Lee & Rio, 2015; Kilchert *et al*, 2016; Bresson & Tollervey,

480 2018). Active transcription could then potentially give rise to the N/C concentration gradient of the preferred

481 TDP-43 binding sites in intronic GU-rich RNAs. The evident nuclear accumulation of newly-synthesized 5-EU-

482 labeled RNAs in HeLa and neurons (**Fig 1A** and **Suppl fig 1A,F**) is indeed consistent with the existence of a

483 steep N/C gradient of U-rich nascent RNAs. Recent rapid advances in CLIP-seq and related methods (Wheeler

484 *et al*, 2018; Hafner *et al*, 2021) have yielded detailed insights into the RNA-RBP interactions and their

485 dynamics (Nostrand *et al*, 2020). Despite this progress, currently available computational methods are not well

486 suited for global quantification of particular sequence motifs (such as GU repeats) across all RNA sequences,

487 although quantitative comparisons within narrowly defined sequence windows are feasible (Boswell *et al*,

488 2017). Thus, direct quantification of the putative N/C gradient of TDP-43 RNA binding sites might require

489 development of new methodological approaches.

490

491 **Biophysical regulation of TDP-43—RNA binding**

492 We observed a drastic reduction in TDP-43 passive nuclear exit from permeabilized cell nuclei at 4°C (**Fig 2B-**

493 **C**), far beyond the approximately two-fold decrease in the passive nuclear import of ERK2-GFP at 4°C in a

494 similar permeabilized cell system (Whitehurst *et al*, 2002), Thus, temperature-dependence of free diffusion

495 alone is unlikely to fully account for the slowing we observed at 4°C. The ability of 1,6-hexanediol to elicit TDP-

496 43 efflux at 4°C (**Fig 2D-E**) suggests that the FG-repeat permeability barrier is temperature-sensitive and likely

497 contributes to the hindrance of TDP-43 passive export at 4ºC. Interestingly, TDP-43 nuclear efflux induced by

498 RNA degradation or GU-rich oligomers was also delayed at 4°C, suggesting temperature sensitivity of TDP-43

499 – RNA binding, which remains to be experimentally verified. RNA-protein interactions generally involve dynamic

500 rearrangements of both binding partners and their stabilization in the complex (Corley *et al*, 2020), suggesting

501 that increased mobility of the complex at a higher temperature may promote TDP-43—RNA dissociation.

502 Consistent with this explanation, molecular dynamics and structural studies indicate that van der Waals forces

503 support the majority of the TDP-43—RNA interaction (Sun *et al*, 2021) as well as the intramolecular

504   interactions of RRM1—RRM2, which have a significant influence on TDP-43—RNA affinity (Lukavsky *et al*,

505   2013). Since van der Waals forces steeply decline with distance of the interacting atoms, a temperature-

506   dependent increase in molecular fluctuation thus could stochastically promote TDP-43 unbinding from nuclear

507   RNAs at 37°C.

508

509   The repertoire of TDP-43 GU-rich RNA binding partners identified by CLIP-seq is structurally diverse

510   (Polymenidou *et al*, 2011; Tollervey *et al*, 2011), and *in vitro* measurements show that TDP-43 binds to

511   different GU-rich RNAs with widely ranging dissociation constants (~3-3000 nM), with the affinity increasing with

512   the number of perfect GU repeats (Bhardwaj *et al*, 2013). The existence of multiple low affinity-binding sites

513   might have a physiological role in TDP-43 auto-regulation (Avendaño-Vázquez *et al*, 2012; Bhardwaj *et al*,

514   2013) and helps to explain the ability of short GU-rich oligomers, which bind TDP-43 *in vitro* with low-nM affinity

515   (Bhardwaj *et al*, 2013; French *et al*, 2019), to displace TDP-43 from endogenous RNAs (**Fig 4D,I**). Although

516   RNase caused a near-complete evacuation of TDP-43 from nuclei in permeabilized cells (**Fig 4B-C**), TDP-43

517   efflux induced by transcriptional blockade (**Fig 1C, Suppl Fig 1C,H,J**) and GU-rich 'decoy' oligomers (**Fig 4I**)

518   showed a time- and dose-dependent plateau in living cells. In addition to ongoing active nuclear import, the

519   existence of an 'export-resistant' nuclear pool of TDP-43 may result from its binding to other nuclear RNAs such

520   as long non-coding RNAs, which constitute a subset of TDP-43 RNA binding partners (Polymenidou *et al*,

521   2011; Tollervey *et al*, 2011) and have been shown to play a role in TDP-43 nuclear LLPS (NEAT 1) (Wang *et*

522   *al*, 2020) and nuclear localization (Malat1) (Nguyen *et al*, 2019). 'Export-resistant' TDP-43 may also represent

523   TDP-43 bound to chromatin or nuclear matrix constituents, as supported by TDP-43 chromatin fractionation

524   data (Ayala *et al*, 2008). Since TDP-43 preferentially binds ssDNA (Buratti & Baralle, 2001), direct binding to

525   genomic DNA is uncertain, but TDP-43 could be indirectly associated with chromatin via protein-protein

526   interactions with histones or other chromatin-associated proteins (Freibaum *et al*, 2010). Indeed, TDP-43 was

527   identified among numerous chromatin-associated RBPs in a recent crosslinking/co-precipitation analysis

528   (Rafiee *et al*, 2021). Nevertheless, a large fraction of endogenous, wild-type TDP-43 in our model systems

529   exhibited nuclear RNA concentration-dependent shuttling.

530

531   **Other physiologic and pathologic factors that may regulate TDP-43 shuttling**

532   Together with NLS-mediated active nuclear import, our results indicate that TDP-43 RRM1,2-dependent pre-

533   mRNA-binding plays a critical role in establishing the steep concentration gradient of TDP-43 across the nuclear

534   envelope (**Fig 6**). Multiple additional physiologic and pathologic processes likely function in parallel to modulate

535   TDP-43 steady-state localization and availability for active or passive nucleocytoplasmic transport. These

536   include oligomerization (Mompeán *et al*, 2017; Afroz *et al*, 2017; French *et al*, 2019), LLPS (Molliex *et al*,

537   2015; Conicella *et al*, 2016; Zacco *et al*, 2018; Mann *et al*, 2019; Conicella *et al*, 2020; Carter *et al*, 2021),

538   alternative splicing to truncated isoforms (Weskamp *et al*, 2020), post-translational modifications, such as

539   phosphorylation, ubiquitination, SUMOylation, acetylation, and C-terminal cleavage (Prasad *et al*, 2019;

540   François-Moutal *et al*, 2019), and pathologic aggregation in disease (Arai *et al*, 2006; Neumann *et al*, 2006).

541   Aberrant maturation of TDP-43 LLPS condensates by seeding (Gasset-Rosa *et al*, 2019) or optogenetic

542   clustering (Mann *et al*, 2019) has been shown to progressively divert the soluble TDP-43 pool into insoluble,

543   high molecular weight cytoplasmic aggregates that seemingly become irreversibly unavailable for nuclear

544   transport. Interestingly, GU-RNA oligomers attenuate recombinant TDP-43 aggregation *in vitro* (French *et al*,

545   2019) and optogenetically-induced cytoplasmic TDP-43 aggregation in living cells (Mann *et al*, 2019),

546   consistent with the notion that access to GU-rich RNAs promotes TDP-43 availability for nucleocytoplasmic

547   shuttling.

548

549   **Disruption of RNA metabolism in ALS/FTD**

550   The observation that GU-rich nuclear pre-mRNAs critically regulate TDP-43 nuclear localization raises the

551   possibility that disruption of nuclear RNA metabolism could contribute to TDP-43 nuclear clearance in ALS/FTD.

552   Indeed, disruption of RNA processing and RNA-based therapy development are of growing interest in the

553   neurodegenerative disease field (Nussbacher *et al*, 2019; Butti & Patten, 2019; Zaepfel & Rothstein, 2021).

554   The status of the GU-rich RNA gradient in TDP-43-mislocalized cells in ALS/FTD is unknown, and few studies

555   to date have examined factors predicted to alter the availability of nuclear GU-rich pre-mRNA binding sites,

556   such as transcription and splicing dynamics or nuclear RNA turnover. However, analysis of genome-wide RNA

557   stability in fibroblasts and induced pluripotent stem cells using metabolic labeling (Bru-seq) demonstrated RNA

558   destabilization in ALS patient-derived cells versus controls (Tank *et al*, 2018). Spliceosomal machinery has

559   also appeared as a common denominator in both knockout and interactome analyses of RBPs implicated in

560 familial ALS/FTD (Chi *et al*, 2018a, 2018b). Further investigation of these factors is warranted as well as N/C

561 transcriptome compartmentalization, which has shown changes in nuclear RNA retention in the context of

562 neuropsychiatric disoders (Price *et al*, 2019), and may provide clues as to perturbation of RNA processing in

563 ALS/FTD. Based on the similar behavior of TDP-43 in HeLa cells and neurons following transcriptional inhibition

564 (**Fig 1 and Suppl fig 1**), it appears likely that the RNA-based regulation of TDP-43 nuclear localization is

565 conserved across somatic and neuronal cells. Moreover, it is tempting to speculate that neuron-specific

566 perturbations in RNA processing/metabolism (Mauger *et al*, 2016; Hermey *et al*, 2017; Jaffrey & Wilkinson,

567 2018; Furlanis *et al*, 2019; Saini *et al.*, 2019; Tyssowski & Gray, 2019; Ling *et al*, 2020) may contribute to

568 cell-specific TDP-43 mislocalization in disease.

569

570 **Conclusion**

571 In summary, nuclear GU-RNA binding and abundance regulate TDP-43 steady-state nuclear localization by

572 dictating availability for passive nuclear export. Further investigation is needed to determine if disruption of RNA

573 metabolism or localization contribute to TDP-43 nuclear clearance in ALS/FTD. Our findings also suggest that

574 RNA-based approaches may be a useful strategy to restore TDP-43 nuclear localization and attenuate TDP-43

575 nuclear loss of function defects in disease.

576

577 **Methods**

Reagent/Resource	Reference or Source	Identifier or Catalog No.
Experimental Models		
HeLa cells (human)	ATCC and (Kalab *et al*, 2006)	HeLa clone 61
TDP-43 CRISPR KO HeLa cells (human)	(Roczniak-Ferguson & Ferguson, 2019)	
HEK293T cells (human)	ATCC	
DLD1-wildtype cells (human)	ATCC and (Aksenova *et al*, 2020)	
DLD1-NXF1-AID cells (human)	ATCC and (Aksenova *et al*, 2020)	
Mouse primary cortical neurons	E16 timed pregnant mice (Jackson laboratory)	
Recombinant DNA		
V5-tagged TDP-43 expression constructs	This study	**See Table 1**
pcDNA3.2 TDP-43 YFP	(Elden *et al*, 2010) via Addgene	Cat #84911

578

579   **Immortalized cell culture**

580   A single cell-derived clone of HeLa cells (ATCC) was maintained in OptiMEM (Gibco/ThermoFisher) with

581   4% FBS and penicillin-streptomycin. HEK293T cells (ATCC) and a monoclonal TDP-43 CRISPR-depleted

582   HeLa cell line (a generous gift from Shawn Ferguson (Roczniak-Ferguson & Ferguson, 2019)), were

583   maintained in DMEM (Gibco/ThermoFisher) with 10% FBS and penicillin-streptomycin. DLD1-wildtype cells

584   (ATCC) and DLD1-NXF1-AID cells (Aksenova *et al.*, 2020) were maintained in DMEM

585   (Gibco/ThermoFisher) with 10% FBS and penicillin-streptomycin. All cell lines were validated by STR

586   profiling, routinely verified to be mycoplasma negative, and frequently refreshed from frozen stocks.

587

Mouse primary cortical neuron culture

589 All animal procedures were approved by the Johns Hopkins Animal Care and Use Committee. Timed

590 pregnant C57BL/6J females (Jackson Laboratory) were sacrificed by cervical dislocation at E16, cortex

591 dissociated, and cells plated at 50,000/well on poly-D-lysine/laminin-coated, optical glass-bottom 96-well

592 plates as described (Hayes *et al*, 2020, 2021). Growth medium consisted of Neurobasal supplemented with

593 B27, Glutamax, and penicillin/streptomycin (Gibco/ThermoFisher).

594

Cloning of recombinant constructs

596 Plasmids for the expression of wild-type (WT) human TDP-43 and its variants in tissue culture cells (**Table**

597 **1**) were prepared by Twist Biosciences via gene synthesis between the HindIII and NheI sites in the

598 pTwistEF1α expression vector. The expected sequences of TDP-43 open reading frames were verified by

599 Sanger sequencing.

600

601 **Table 1. TDP-43 constructs**

Expressed protein	TDP-43 amino acids	Point mutations	Predicted size (kD)	ID #
WT TDP-43-V5	1-414	none	44.7	pK1194
TDP-43 (ΔRRM1,2)-V5	1-105; 260-414	none	28.9	pK1195
TDP-43 (2KQ)-V5	1-414	K145Q, K192Q	44.7	pK1196
TDP-43 (5FL)-V5	1-414	F147L, F149L,F194L,F229L,F231L	44.7	pK1197

602

RNA oligonucleotides

604 Synthetic RNA oligonucleotides (**Table 2**) were obtained from IDT in the form of desalted lyophilized powder.

605 Upon reconstitution in sterile, RNAse and DNAse -free water, single use aliquots were stored at -70°C.

606

607 **Table 2. RNA oligonucleotides**

608

609 **Permeabilized cell TDP-43 export assays**

610 HeLa cells were plated on Matrigel-coated optical glass-bottom 96 well plates (CellVis), at 12,000-15,000 cells

611 per well targeting 80-90% confluence at 24 h. To permeabilize, cells were rinsed for 2 min in ice-cold PBS, and

612 permeabilized on ice for 10 min in 25-35 ug/mL digitonin (Calbiochem) in transport buffer (TRB, 20 mM HEPES,

613 110 mM KOAc, 2 mM Mg(OAc)$_2$, 5 mM NaOAc, 0.5 mM EGTA, 250 mM sucrose, pH 7.4, with freshly added

614 Halt protease inhibitor (1:100, Promega)). The optimal digitonin concentration varied by cell density and

615 passage number and was optimized prior to each assay such that the majority of plasma membranes were

616 permeabilized while maintaining nuclear exclusion of a 70 kD fluorescent dextran (ThermoFisher). The

617 permeabilized cells were washed twice in ice-cold TRB prior to initiating the export assay.

618

619 Assay components, including 1,6-hexanediol (Sigma-Aldrich), ATP (pH 7.5, Sigma-Aldrich), RNase A

620 (ThermoFisher), or RNA oligomers (**Table 2,** synthesized by IDT or Sigma-Aldrich) were premixed in TRB in 96-

621 well plates and equilibrated at the appropriate temperature (4ºC, 25ºC, or 37ºC) prior to cell permeabilization.

622 With the exception of RNase A-containing assays, TRB was routinely supplemented with RNasin Ribonuclease

623 Inhibitor (1000 U/mL, Promega). Following permeabilization, the assay mix was transferred onto permeabilized

624 cells via multichannel pipette and export was allowed to proceed at the temperature (4ºC, 25ºC, or 37ºC) and

625 for the time (30-60 min) indicated in the figure legends, prior to fixation in 4% paraformaldehyde/PBS (Electron

626 Microscopy Sciences) for 15 min. For each replicate, an additional plate of cells was fixed immediately post-

627 permeabilization, designated 'time 0', for the purpose of data normalization across independent biological

628 replicates.

629

630 **Permeabilized cell Rango nuclear import assay**

631 Synthesis and nuclear import of the recombinant Rango sensor was carried out as recently described (Hayes

632 *et al*, 2020, 2021). Briefly, following HeLa cell permeabilization as above, Rango nuclear import assays were

633   carried out with or without 2.5 mM ATP (pH 7.5, Sigma-Aldrich) and HEK whole cell lysate (2.5 mg/mL in TRB),

634   at 37ºC for 30 minutes. A subset of assays included recombinant human importin β (71-876), a RanGTP-

635   resistant variant (Drutovic *et al*, 2020). Cells were fixed for 15 min in 4% paraformaldehyde/PBS, washed 2x

636   with PBS containing Hoechst (1:5000), and transferred to 50% glycerol/PBS for immediate imaging.

637

638   **Live-cell TDP-43 shuttling assays**

639   HeLa and DLD1 cells were plated in uncoated, optical glass-bottom 96-well plates (CellVis) to achieve

640   ~75% confluence at the time of shuttling assays. For transcriptional inhibition, TDP-43 shuttling was

641   initiated by treatment with actinomycin D (Sigma-Aldrich, in DMSO) or NVP-2 (Tocris Bioscience, in

642   DMSO) at doses/times indicated in the figure legends. For splicing inhibition, cells were pretreated for 4 h

643   with escalating doses of isoginkgetin (IGK, Millipore-Sigma, in DMSO) or pladienolide B (PLB, Cayman

644   Chemicals, in DMSO), prior to addition of 250 nM NVP-2. For NXF1 ablation experiments, DLD1-wildtype

645   and DLD1-NXF1-AID cells were pretreated for 0-8 hrs with 0.5 mM synthetic auxin (3-indoleacetic acid,

646   Sigma, in ethanol), prior to addition of 250 nM NVP-2. At the conclusion of experiments, cells were fixed in

647   4% paraformaldehyde/PBS (Electron Microscopy Sciences) for 15 minutes prior to immunostaining.

648

649   **Immunofluorescence**

650   Paraformaldehyde-fixed cells were rinsed with PBS and simultaneously permeabilized and blocked with 0.1%

651   Triton-X 100 and 10% normal goat serum (NGS, Vector Labs) in PBS for 30 min at room temperature. Primary

652   antibody in 10% NGS/PBS was added to the cells and incubated for 60-90 min at room temperature or

653   overnight at 4ºC. Cells were rinsed 2x with PBS and AF488 or AF647-labeled secondary antibody

654   (ThermoFisher) was added in 10% NGS/PBS and incubated for 1 h at room temperature. Cells were rinsed with

655   PBS containing Hoechst 33342 and transferred to 50% glycerol/PBS for imaging.

656

657   **RNA labeling**

658   For poly(A)-fluorescence in situ hybridization (FISH), cells were fixed in 10% formaldehyde (Sigma-Aldrich) in

659   PBS for 20 min, permeabilized in 0.1% PBS-Tween for 10 min, and washed 3 times in 1x PBS and 2 times in 2x

660   SSC buffer (Sigma-Aldrich) for five min each. Cells were prehybridized for 1 h in hybridization buffer at 42°C

661 (Thermo), and then incubated in Cy3-oligo-dT(45) probe (IDT, 100 nM in hybridization buffer) overnight at 42°C.

662 Cells were washed with decreasing concentrations of SSC buffer at 42°C (2x, then 0.5x, then 0.1x in PBS, for

663 20 min each), with Hoechst 33342 nuclear counterstain included in the final wash.

664

665 For click-chemistry labeling of nascent RNA synthesis, cells were treated with 200 µM 5-ethynyl-uridine in

666 culture media for 30 min, fixed with 4% paraformaldehyde/PBS for 15 min, permeabilized and blocked in 2%

667 BSA/0.1%Tx-100 in PBS for 30 min, and labeled with 0.5 µM AF488-Picolyl Azide using the Click-&-Go Cell

668 Reaction Buffer kit according to the manufacturers' instructions (all reagents from Click Chemistry Tools). Cells

669 were subsequently immunolabeled for TDP-43 as described above.

670

671 **High content imaging and data analysis**

672 Automated imaging and analysis were carried out using an ImageXpress Micro Confocal high content

673 microscope with MetaXpress software (Molecular Devices) as previously described (Hayes *et al*, 2020, 2021).

674 Briefly, nine non-overlapping fields per well were imaged at 20x (immortalized cells) or 40x (neurons)

675 magnification in spinning disc confocal mode with 60 µm pinhole, with exposures targeting half-maximal

676 saturation (33,000 / 65,536 relative fluorescent units (RFU) in unbinned, 16-bit images). The background-

677 corrected mean and integrated nuclear and cytoplasmic intensities and the nuclear/cytoplasmic (N/C) ratio were

678 calculated using the translocation-enhanced module. Number and morphometry of nuclear puncta were

679 calculated using the granularity module. The Hoechst counterstain was used to identify the nuclear/cytoplasmic

680 boundary and nuclear and cytoplasmic compartments were set several pixels in and outside of the nuclear

681 boundary to avoid edge effects. All image analysis was carried out on raw, unaltered images. Raw data were

682 uniformly filtered to exclude errors of cell identification (probe intensity = 0) and non-physiologic N/C ratios (N/C

683 <0.1 or >100). For transient transfections, data were filtered by mean intensity to exclude untransfected cells

684 (<1000 RFU) and highly expressing cells (>45,000 RFU). Resulting data were normalized across technical and

685 biological replicates as percent untreated controls or percent time 0, as indicated in the figure legends. The

686 mean number of cells/well across replicates is also provided. The number of biological replicates (independent

687 cell passages/experiments) was used as the N for statistical analyses.

688

689 **qPCR**

690 Cells were rinsed in PBS and lysed in TRIzol (ThermoFisher). Total RNA was isolated following the

691 manufacturer's protocol and resuspended in nuclease-free water. First-strand cDNA synthesis was

692 performed with 1ug of total RNA using the High-Capacity cDNA Reverse Transcription Kit (ThermoFisher).

693 qPCR was performed using PowerSYBR Green PCR Master Mix (ThermoFisher) with 10ng of cDNA per

694 well and exon-intron primers (500nM) as listed below, using a QuantStudio 3 Real-Time PCR System.

695

696 **Nuclear/cytoplasmic fractionation and immunoblotting**

697 24-48 h post-transfection with V5-tagged TDP-43 and RRM mutants, TDP-43 CRISPR KO HeLa cells were

698 lysed for N/C fractionation and SDS-PAGE with the NE-PER kit (ThermoFisher) according to the

699 manufacturer's instructions. Total protein concentration was measured using the DC Protein Assay kit (Bio-

700 Rad). Nuclear (5 µg total protein) and cytoplasmic (10 µg total protein) fractions were boiled in Laemmli

701 buffer (Bio-Rad), run on Criterion 4-20% Gels (Bio-Rad), and transferred to nitrocellulose membranes using

702 a TransBlot Turbo system (BioRad). Membranes were blocked with 5% non-fat milk in TBS-Tween and

703 probed by sequential incubation in primary antibody overnight at 4°C. Detection was via HRP-conjugated

704 secondary antibodies/chemiluminescence using an ImageQuant LAS 4000 system (GE). Band intensities

705 were measured using ImageQuant software.

706

707 **ATP quantification**

708 Permeabilized and live cells in TRB were lysed and ATP levels quantified using the CellTiter-Glo luminescence

709 assay (Promega) according to the manufacturers' instructions. Luminescence was measured using a

710 SpectraMax M3 microplate reader (Molecular Devices).

711

712 **Image processing for figures**

713 Immunofluorescence images were cropped and minimally processed for figures using Adobe Photoshop

714 2021(v22.4.3) as follows and as indicated in the figure legends. For the purpose of raw intensity comparisons,

715 including the nascent RNA signal (**Fig 1** and **Suppl fig 1**) and the TDP-43 nuclear signal in permeabilized cells

716 (**Fig 2, 4**), the intensity histogram of the designated control was maximized based on the brightest and dimmest

717   pixels, and those parameters were subsequently applied to all other images. For comparisons of shifts in the

718   N/C ratio (all other figures), the intensity histogram was independently maximized according to the brightest and

719   dimmest pixels in each image, to enable adequate visualization of both the nuclear and cytoplasmic

720   compartments. To aid in data visualization, in selected images the fire pseudo-color LUT was applied using

721   FIJI/ImageJ (v2.1.0/1.53c) and the quantitative/linear map is provided in the image. All adjustments were linear

722   (no gamma changes) and applied equally to the entire image. Immunoblots were cropped for space and no

723   other processing was applied. Uncropped immunoblot images are provided in the source data.

724

725   **Statistical analysis**

726   Graphing and statistical analyses were carried out using Prism v9.2.0 (Graphpad), according to the

727   methods detailed in the figure legends.

728

729

730   **FIGURE LEGENDS**

731

732   **Figure 1. NVP-2-induced RNA Pol II inhibition promotes TDP-43 nuclear export**

733   A. Newly-synthesized RNAs labeled with AF488-picolyl azide via 5-EU incorporation/'click chemistry' (top)

734   and TDP-43 immunofluorescence (bottom) in HeLa cells treated with DMSO (vehicle) vs. NVP-2 for 1 h.

735   Arrows indicate rRNA puncta unaffected by NVP-2. Scale bar = 25 μm.

736   B, C. High content analysis of nascent RNA (AF488-azide) mean nuclear intensity (B) and TDP-43 nuclear

737   to cytoplasmic (N/C) ratio (C) expressed as percent DMSO control. N = mean of 2442 cells/well in each of

738   3 independent biological replicates. Mean ± SD is shown. The IC_{50} for 1 h treatment is indicated, as

739   calculated by non-linear regression.

740   D. RBP N/C ratios in HeLa cells treated with 250 nM NVP-2 for 30 min to 6 h. Selected proteins are labeled

741   (the full panel is detailed in **Suppl fig 2**). N = mean of 2716 cells/well. Curves were fit by non-linear

742   regression using the mean of 2-4 biological replicates per RBP.

743

744 **Supplemental figure 1. Transcriptional blockade-induced TDP-43 nuclear export in HeLa and**

745 **neurons**

746 A. Nascent RNAs labeled with AF488-picolyl azide via 5-EU incorporation/'click chemistry' (top) and TDP-

747 43 immunofluorescence (bottom) in HeLa cells treated with DMSO (vehicle) vs. Actinomycin D for 1 h.

748 Scale bar = 25 µm.

749 B, C. High content analysis of nascent RNA (AF488-azide) mean nuclear intensity (B) and TDP-43 nuclear

750 to cytoplasmic (N/C) ratio (C) expressed as percent DMSO control. N= mean of 2540 cells/well. Mean ± SD

751 of 3-4 biological replicates per condition is shown. The IC_{50} for 1 h treatment is indicated, as calculated by

752 non-linear regression.

753 D, E. Mean nuclear vs. cytoplasmic intensity of TDP-43 following NVP-2 (D) or Actinomycin D (E)

754 treatment. These are the source data that were used to calculate the N/C ratios in **Fig 1B,C** and **Suppl**

755 **figure 1B,C**. The IC_{50} for 1 h treatment is indicated, as calculated by non-linear regression.

756 F. Nascent RNAs labeled with AF488-picolyl azide via 5-EU incorporation/'click chemistry' (top) and TDP-

757 43 immunofluorescence (bottom) in mouse primary cortical neurons cells treated with DMSO (vehicle), 250

758 nM NVP-2, or 1 µM Actinomycin D for 3 h. Arrows indicate rRNA puncta unaffected by NVP-2. Scale bar =

759 25 µm.

760 G-J. High content analysis of nascent RNA (AF488-azide) mean nuclear intensity and TDP-43 nuclear to

761 cytoplasmic (N/C) ratio in primary neurons treated with NVP-2 (G,H) or Actinomycin D (I,J), expressed as

762 percent DMSO control. N= mean of 534 cells/well in each of of 2 biological replicates. Mean ± SD is shown.

763 K. Raw N/C ratio of endogenous TDP-43 vs. TDP-43-YFP and TDP-43-V5 in transiently transfected HeLa

764 cells following 1-4 h treatment with 250 nM NVP-2. N= mean of 2070 cells/well in each of of 3 biological

765 replicates. Mean ± SD is shown.

766

767 **Supplemental figure 2. Comparison of NVP-2-induced shuttling among RBPs**

768 A. RBP N/C ratios in HeLa cells after 30 min (left) or 6 h (right) of 250 nM NVP-2 treatment, expressed as

769 % time 0. N= mean of 2716 cells/well. Mean of 2-4 biological replicates per protein is shown.

770 B. RBP immunostaining in NVP-2-treated HeLa cells at designated timepoints following NVP-2 exposure.

771 Scale bar = 50 µm.

772

773   **Figure 2. TDP-43 exits the nucleus by passive diffusion in permeabilized cells**

774   A. Schematic of permeabilized cell TDP-43 passive nuclear export assay. IF = immunofluorescence.

775   B. TDP-43 immunofluorescence (top) and Hoechst nuclear stain (bottom) in permeabilized HeLa cells fixed

776   immediately post-permeabilization (0 min) and 60 min post-permeabilization, following incubation at 4°C or

777   37°C. The intensity histogram for all TDP-43 images was normalized relative to the 0 min control, prior to

778   application of the pseudo-color LUT (middle) to illustrate relative TDP-43 nuclear intensity. Scale bar = 50

779   μm.

780   C. Integrated nuclear intensity of TDP-43 in permeabilized HeLa cells over time at 4°C vs. 37°C expressed

781   as percent of time 0. N = mean of 2185 cells/well/condition in each of 4 independent biological replicates.

782   D. TDP-43 immunofluorescence staining (top) and Hoechst nuclear stain (bottom) in permeabilized HeLa

783   cells incubated for 30 minutes post-permeabilization at 4°C vs. 37°C with increasing concentrations of 1,6-

784   hexanediol. The intensity histogram for all TDP-43 images was normalized relative to 0% HD (4°C). Scale

785   bar = 50μm.

786   E. Integrated nuclear intensity of TDP-43 in permeabilized HeLa cells incubated for 30 minutes at 4°C vs.

787   37°C with increasing concentrations of 1,6-hexanediol. Data are expressed as percent untreated, 4°C. N =

788   mean of 2389 cells/well/condition in each of 3 independent biological replicates.

789   In C, E, **p<0.01, ***p<0.001, ****p<0.0001 by 2-way ANOVA with Tukey's multiple comparisons test.

790

791   **Supplemental figure 3. Validation of permeabilized cell passive export assay.**

792   A. Evaluation of nuclear pore and nuclear membrane integrity by exclusion of 70 kD Texas Red-dextran in

793   digitonin-permeabilized HeLa cells in transport buffer. Scale bar = 20 μm.

794   B. ATP luciferase assay in intact versus digitonin-permeabilized HeLa cells, measured immediately

795   following digitonin permeabilization. N=3 independent biological replicates. ****p<0.0001 by unpaired

796   Student's t-test.

797   C. TDP-43 integrated nuclear intensity in permeabilized HeLa cells incubated for 30 min at 37°C with or

798   without 100 nM Leptomycin B (LMB) treatment during permeabilization, wash, and export phases. Data are

799   expressed as percent time 0. N = mean of 3005 cells/well in each of 6 technical replicates.

800   D. TDP-43 integrated nuclear intensity in permeabilized HeLa cells incubated for 30 min at 37°C with

801   increasing concentrations of ATP (0 to 2 mM). Data are expressed as percent time 0. N = mean of 2883

802   cells/well/condition in each of 3 independent biological replicates. NS = not significant, one-way ANOVA

803   with Tukey's post-hoc test.

804   E. Rango integrated nuclear intensity in permeabilized HeLa cells incubated for 30 min at 37°C with or

805   without HEK cell lysate, ATP (2.5 mM), and dominant-negative importin-β (71-876) mutant. Data are

806   expressed as percent untreated (dotted line). N = mean of 1289 cells/well in each of 2 technical replicates.

807

808   **Figure 3. Acute NXF1 ablation does not alter NVP-2-induced TDP-43 nuclear export**

809   A. NXF1 immunoblot in DLD1-wild-type vs. DLD1-NXF1-AID cells treated with 0.5 mM auxin for 0-4 h. Note

810   the increased molecular weight for AID-tagged NXF1 (*) vs endogenous NXF1 (>).

811   B. Poly(A)-FISH (Cy3-OligodT(45)) in DLD1-wild-type vs. DLD1-NXF1-AID cells treated with 0.5 mM auxin

812   for designated time. Scale bar = 25 μm.

813   C. Poly(A)-RNA N/C ratio in DLD1-wild-type vs. DLD1-NXF1-AID cells treated with 0.5 mM auxin for 0-8 h.

814   Data are expressed as percent wild-type untreated cells. N = mean of 3476 cells/well in each of 4

815   independent biological replicates. Mean ± SD is shown. *p<0.05, ****p<0.0001 versus wild-type, by 2-way

816   ANOVA with Sidak's multiple comparisons test.

817   D. TDP-43 N/C ratio in DLD1-wild-type cells (left) and DLD1-NXF1-AID cells (right) pretreated with 0.5 mM

818   auxin for 0-8 h, followed by 2 h auxin only (-NVP-2) or auxin + 250 nM NVP-2 (+NVP-2). Data in both

819   panels are normalized to untreated DLD1-wild-type cells (dotted line).

820   E. TDP-43 N/C ratio in NVP-2 treated vs. untreated cells (+NVP-2 / -NVP-2) in DLD1-wild-type (black) vs.

821   DLD1-NXF1-AID (red) cells. These are the same data as in (D), adjusted for differences in the steady-state

822   TDP-43 N/C ratio, to permit comparison of NVP-2-induced TDP-43 nuclear exit.

823   In D-E, N = mean of 4610 cells/well in each of 4 independent biological replicates. Mean ± SD is shown.

824   ****P<0.0001 for indicated comparisons by 2-way ANOVA with Sidak's multiple comparisons test.

825

826   **Figure 4. RNase and GU-rich oligomers induce TDP-43 nuclear efflux**

A. Schematic depicting addition of RNase (A-C) or RNA oligomers (D-G) to permeabilized cell TDP-43 passive export assay.

B. Endogenous TDP-43 immunofluorescence (top) and Hoechst (bottom) in permeabilized HeLa cells incubated for 30 min at 4°C with or without RNase A. Arrows highlight formation of nuclear puncta by residual nuclear TDP-43. Scale bar = 25 µm.

C. TDP-43 integrated nuclear intensity in permeabilized HeLa cells incubated for 30 min at 4°C vs. 37°C with increasing concentrations of RNase A. Data are expressed as percent untreated cells at 4°C. N = mean of 2552 cells/well/condition in each of 4 independent biological replicates. ****p<0.0001 versus time 0 by 2-way ANOVA with Tukey's multiple comparisons test.

D. TDP-43 integrated nuclear intensity in permeabilized HeLa cells incubated for 30 min at 4°C with increasing concentrations of A16, (GU)8, or 'AUG12' oligomers. Data are expressed as percent untreated cells. N = mean of 2968 cells/well/condition in each of 4 independent biological replicates.

E. TDP-43 integrated nuclear intensity in permeabilized HeLa cells incubated at 4°C, 25°C or 37°C for 30 min with increasing concentrations of (GU)8. Data are expressed as percent untreated cells. N = mean of 1039 cells/well/condition in each of 2 technical replicates.

F. Integrated nuclear intensity of designated nuclear RBPs in permeabilized HeLa cells incubated for 30 minutes at 4°C with increasing concentrations (GU)8. Data are expressed as percent untreated cells. Note: TDP-43 data are the same as in (D). N = mean of 3421 cells/well in each of 4 independent biological replicates.

G. Integrated nuclear intensity of designated nuclear RBPs in permeabilized HeLa cells incubated for 30 minutes at 4°C with increasing concentrations of the indicated RNA oligomers. Data are expressed as percent untreated cells. N = mean of 3293 cells/well/condition in each of 3-4 independent biological replicates.

H. Schematic of live HeLa cell transfection with protected RNA oligomers.

I. TDP-43 N/C ratio 5 h after transfection with protected A13 or (GU)6 RNA oligomers. Data are expressed as percent untreated cells. N = mean of 2887 cells/well/condition in each of 3 independent biological replicates.

854   J. RBP N/C ratios 5 h after transfection with protected (GU)6 RNA oligomers. Data are expressed as

855   percent untreated cells. Note: TDP-43 data are the same as those shown for (GU)6 in (I). N = mean of

856   2555 cells/well/condition in each of 3 independent biological replicates.

857   In F,G,J: The RBP labeled in red corresponds to the most closely-predicted binding partner for that motif,

858   and green indicates an RBP with a moderately-similar motif. Gray and black labels correspond to RBPs

859   with no or low predicted binding activity to the given sequence.

860   In D-J: RNA oligomer sequences are detailed in **Table 2**. Mean ± SD is shown. IC50 values were

861   calculated by non-linear regression.

862

863   **Supplemental figure 4. Nuclear and RNA integrity controls.**

864   A. Integrated nuclear intensity of DDX19b and Nup50 versus TDP-43 in permeabilized HeLa cells

865   incubated for 30 minutes at 4°C (left) or 37°C (right) with increasing concentrations of RNase A. Data are

866   expressed as percent untreated cells. N = mean of 2868 cells/well in each of 3 technical replicates. Mean ±

867   SD is shown.

868   B. Integrated nuclear intensity of TDP-43 in permeabilized HeLa cells incubated for 30 or 60 min at 37°C

869   with or without RNasin ribonuclease inhibitor. Data are expressed as percent time 0, untreated cells. N =

870   mean of 3262 cells/well in each of 2 independent replicates.

871

872   **Figure 5. Inhibition of pre-mRNA splicing promotes TDP-43 nuclear accumulation**

873   A. TDP-43 immunofluorescence in HeLa cells treated with IGK for 4 h, followed by 2 h of IGK only or IGK +

874   250 mM NVP-2. Scale bar = 25 μm.

875   B. TDP-43 N/C in IGK or IGK + NVP-2-treated cells, expressed as % untreated.

876   C. TDP-43 N/C ratio (same data as part B) expressed as % IGK only, to permit comparison of NVP-2-

877   induced nuclear exit. IC_{50} calculated by non-linear regression.

878   D. TDP-43 immunofluorescence in HeLa cells treated with PLB for 4 h, followed by 2 h of PLB only or PLB

879   + 250 mM NVP-2. Scale bar = 25 μm.

880   E. TDP-43 N/C in PLB or PLB + NVP-2-treated cells, expressed as % untreated.

881   F. TDP-43 N/C ratio (same data as part E) expressed as % PLB only, to permit comparison of NVP-2-

882   induced nuclear exit. IC_{50} calculated by non-linear regression.

883   In A,C: The intensity histogram for each image was independently maximized across the full range to

884   enable comparison of nuclear vs. cytoplasmic signal, and a pseudo-color LUT was then applied (see linear

885   scale at right).

886   In B,C: N= mean of 2357 cells/well in each of 4 independent biological replicates. Mean ± SD is shown.

887   In E,F: N= mean of 2720 cells/well in each of 4 independent biological replicates. Mean ± SD is shown.

888   In B,C,E,F: ***$p < 0.001$, ****$p < 0.0001$ by 2-way ANOVA with Tukey's multiple comparisons test.

889   Comparisons as indicated with untreated cells (brackets) or between NVP-2-treated and untreated cells at

890   each dose of splicing inhibitor (no brackets).

891   See **suppl fig 5** for validation of IGK and PLB-induced intron accumulation by qRT-PCR.

892

893   **Supplemental figure 5. Validation of IGK and PLB-induced intron accumulation**

894   A-C. qRT-PCR quantification of β-tubulin (A), actin (B), and DNAJB1 (C) pre-mRNAs using exon-intron

895   primer pairs, normalized to U6 snRNA expression. HeLa cells were treated for 4 h with IGK or PLB at

896   indicated doses. Mean ± SD is shown for N=2 technical replicates.

897

898   **Figure 6. Mutation or deletion of TDP-43 RRM domains disrupts TDP-43 nuclear localization**

899   A. Schematic of V5-tagged TDP-43 RRM mutant constructs (top) and V5 immunofluorescence (bottom) in

900   transiently transfected TDP-43 CRISPR KO HeLa cells, after 1 h treatment with DMSO vs. 250 nM NVP-2.

901   The intensity histogram for each image was independently maximized across the full range to enable

902   comparison of nuclear vs. cytoplasmic signal, and a pseudo-color LUT was then applied (see linear scale

903   at right). See **suppl fig 6** for validation of CRISPR knockdown of endogenous TDP-43. Scale bar = 25 μm.

904   B. Raw N/C ratio of TDP-43 wild-type vs. RRM mutant constructs in transiently transfected TDP-43

905   CRISPR KO HeLa cells, following 1 h treatment with DMSO or 250 nM NVP-2. N= mean of 1015 cells/well

906   in each of 4 replicates (2 technical and 2 biological). Mean ± SD is shown.

907   C. N/C fractionation and immunoblotting of TDP-43 CRISPR KO HeLa cells, transiently transfected with

908   V5-tagged TDP-43 constructs and treated for 3 h with DMSO vs. 250 nM NVP-2. Lamin B1 = nuclear

909   marker. GAPDH = cytoplasmic marker.

910   D. N/C ratio of V5 nuclear vs. cytoplasmic signal calculated from N=3 immunoblots (derived from 2

911   biological replicates). Ratios are expressed as % WT DMSO-treated cells.

912   In B,D: ns = not significant, ****$p<0.0001$ by 2-way ANOVA with Tukey's multiple comparisons test.

913

914   **Supplemental figure 6. TDP-43 CRISPR KO cell validation and effect of HSP70i on TDP-43**

915   **granularity and nuclear localization.**

916   A. TDP-43 gene expression in wild-type vs. CRISPR KO HeLa cell lines by qRT-PCR, normalized to

917   GAPDH expression. N=3 technical replicates.

918   B. Immunoblot comparing endogenous TDP-43 protein expression in wild-type vs. CRISPR KO HeLa cells

919   (left). Level of expression of transiently transfected V5-tagged constructs vs. endogenous TDP-43, and

920   immunodetection by TDP-43 (left) and V5 (right) antibodies is also shown.

921   C. YFP epifluorescence in TDP-43 CRISPR KO cells transiently transfected with TDP-43-5FL-YFP, before

922   and after 3 h treatment with HSP70i (50 μM). Arrows highlight examples of reduction in number of nuclear

923   granules. Note that moderate cell migration occurs over the timecourse of the assay. Scale bar = 50 μm.

924   D. High content analysis of number of TDP-43-YFP and TDP-43-5FL-YFP granules per nucleus in DMSO

925   vs. HSP70i-treated cells, assessed via live, time-lapse imaging. N = mean of 2171 cells/well/condition in

926   each of two independent biological replicates. Mean ± SD is shown.

927   E. V5 immunofluorescence in TDP-43 CRISPR KO cells transiently transfected with V5-tagged wild-type

928   and RRM mutant TDP-43 constructs, and treated for 3 h with DMSO vs. HSP70i (50 μM). Note: Rare

929   examples of puncta-containing nuclei are shown (arrows) which constitute only a minority of the cell

930   population as quantified in (F). The intensity histogram for each image was independently maximized

931   across the full range. Given the intense fluorescence of the puncta, this prevents visualization of the N/C

932   gradients which are better appreciated in the more representative images in **Fig 6A**. Scale bar = 25 μM.

933   F-H. High content granularity analysis in TDP-43 CRISPR KO cells transiently transfected with V5- or YFP-

934   tagged wild-type and RRM mutant TDP-43 constructs, and treated with DMSO or HSP70i (50 μM) for 3h.

935   Parameters include % cells with ≥ 1 puncta (F), # puncta/nucleus (G, expressed as % DMSO), and mean

936   puncta area (H, expressed as % DMSO). N = mean of 1156 cells/well/condition in each of three

937   independent biological replicates. Mean ± SD is shown.

938   I. N/C ratio of V5 immunofluorescence signal, in TDP-43 CRISPR KO cells transiently transfected with V5-

939   tagged wild-type and RRM mutant TDP-43 constructs, and treated with DMSO, NVP2 (250 nM), HSP70i

940   (50 μM), or both for 3h. Data are expressed as percent wild-type DMSO-treated cells. N = mean of 788

941   cells/well/condition in each of three independent biological replicates.

942   In F-I: ns = not significant, *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001 for designated comparisons by 2-

943   way ANOVA with Sidak's multiple comparisons test.

944

945   **Figure 7. Mechanisms coupling TDP-43 nuclear localization with nuclear GU-rich pre-mRNA binding**

946   **and abundance.** Arrow size corresponds to predicted balance under normal physiologic conditions. See

947   text for discussion.
