12 **Abstract**

13 *Phomopsis* sp. XP-8, an endophytic fungus from the bark of Tu-Chung (*Eucommia*
14 *ulmoides* Oliv), revealed the pinoresinol diglucoside (PDG) biosynthetic pathway after precursor
15 feeding measurements and genomic annotation. To verify the pathway more accurately, [¹³C₆]-labeled
16 glucose and [¹³C₆]-labeled phenylalanine were separately fed to the strain as sole substrates and
17 [¹³C₆]-labeled products were detected by ultra-high performance liquid chromatography-quantitative
18 time of flight mass spectrometry. As results, [¹³C₆]-labeled phenylalanine was found as
19 [¹³C₆]-cinnamylic acid and *p*-coumaric acid, and [¹³C₁₂]-labeled pinoresinol revealed that the
20 pinoresinol benzene ring came from phenylalanine via the phenylpropane pathway. [¹³C₆]-Labeled
21 cinnamylic acid and *p*-coumaric acid, [¹³C₁₂]-labeled pinoresinol, [¹³C₁₈]-labeled pinoresinol
22 monoglucoside (PMG), and [¹³C₁₈]-labeled PDG products were found when [¹³C₆]-labeled glucose
23 was used, demonstrating that the benzene ring and glucoside of PDG originated from glucose. It was
24 also determined that PMG was not the direct precursor of PDG in the biosynthetic pathway. The study
25 verified the occurrence of the plant-like phenylalanine and lignan biosynthetic pathway in fungi.

26 **Keywords:** [¹³C₆]-labeled glucose, [¹³C₆]-labeled phenylalanine, Q-TOF-MS,
27 phenylalanine biosynthetic pathway, lignan

28
29 **Importance:** Verify the phenylpropanoid-pinoresinol biosynthetic pathway and its glycosides in an
30 endophytic fungi.

31 Introduction

32 Pinoresinol diglucoside (PDG), (+)-1-pinoresinol 4, 4' -di-O- β -D-glucopyranoside, is a major
33 antihypertensive compound found in Tu-Chung, a traditional herb medicine with excellent efficacy for
34 lowering blood pressure (1, 2). PDG possesses the potential to prevent osteoporosis (3). PDG is
35 converted to enterolignans by intestinal microflora (4); thus, showing potential to reduce the risk of
36 breast cancer (5) and other estrogen-dependent cancers (6).

37 PDG is found primarily in plants as lignans (1,7) but yields are very low. *Phomopsis* sp. XP-8 is
38 an endophytic fungus isolated from the bark of Tu-Chung that was previously found to produce PDG
39 *in vitro* (8); thus, providing an alternative resource to obtain PDG. This is the first report on the
40 capability of a microorganism to synthesize lignan. However, production was also very low. Therefore,
41 it is essential to identify the PDG biosynthetic pathway in this strain.

42 The lignan biosynthetic pathway has only been reported in plants until now (9,10). Synthesis of
43 pinoresinol (Pin) in plants occurs via oxidative coupling of monolignols, which are synthesized through
44 the phenylpropanoid pathway with phenylalanine (Phe), cinnamic acid, *p*-coumarate, *p*-coumaroyl-CoA,
45 caffeate, ferulate, feruloyl-CoA, coniferylaldehyde, and coniferyl alcohol as intermediates or precursors
46 (11, 12) (Fig.1). Pinoresinol monoglucoside (PMG) and PDG are converted from Pin by
47 UDP-glucose-dependent glucosyltransferase (13). However, the biosynthesis of PDG from Pin has not
48 been detected in plants and the Pin, PMG, and PDG biosynthetic pathways have not been illustrated in
49 microorganisms.

50 We previously reported that *Phomopsis* sp. XP-8 converts mung bean starch and polysaccharides
51 to Pin, PMG, and PDG. Phe, cinnamic acid, and *p*-coumaric acid have been detected as products of the
52 bioconversion (14,15). Precursor feeding and enzymatic activity measurements indicate that this strain
53 synthesizes PDG via many steps, such as during mass flow of the phenylpropanoid pathway (16).
54 Genomic annotation indicates that the phenylpropane pathway exists in this strain (17) and some other
55 microorganisms (18). However, the functions of the denoted genes have not been verified until now.
56 Therefore, it is necessary to verify the entire PDG biosynthetic pathway in *Phomopsis* sp. XP-8.

57 Using stable or radioactive isotope-labeled compounds is an efficient and reliable strategy to
58 verify the mass flow of unknown biosynthetic pathways by tracing the isotope-labeled compounds
59 from substrates to products (19). ^{13}C -labeled substrates have been used to shed light on the
60 biodegradation pathways of organic pollutants (20). Isotope labeling combined with high-resolution

61 mass spectrometry have also been used to track the abiotic transformation of pollutants in aqueous
62 mixtures (21). In recent years, liquid chromatography-mass spectrometry (LC-MS) and ultra-high
63 performance liquid chromatography (UPLC) systems have been developed to facilitate the analysis of
64 many substances at the same time with high sensitivity and selectivity (22). Stable isotope-labeled
65 compounds have also been employed in several areas of biomedical research (23). The combination of
66 stable isotope-labeling techniques with MS has allowed rapid acquisition and interpretation of data and
67 has been used in many fields, including distribution, metabolism, food, and excretion studies (24, 25,
68 26). The biochemical pathway of the aromatic compounds in tea has been also been revealed using the
69 stable isotope labeling method (27).

70 In this study, we applied stable isotopes and MS to trace the PDG biosynthetic pathway. $^{13}\text{C}_6$
71 stable isotope-labeled glucose and $^{13}\text{C}_6$ Phe were used as the substrates and electrospray
72 ionization-quantitative time of flight tandem mass spectrometry (ESI-Q-TOF-MS/MS) was used to
73 identify the products.

74 **Materials and methods**

75 **Microorganism and chemicals**

76 *Phomopsis* sp. XP-8 previously isolated from the bark of Tu-Chung and stored at the China Center
77 for Type Culture Collection (Wuhan, China) (code: *Phomopsis* sp. CCTCC M 209291) was used in the
78 study.

79 Phe (purity \geq 98%, Sigma, St. Louis, MO, USA), cinnamic acid and *p*-coumaric acid (purity \geq
80 98%; Aladdin, Shanghai, China), PDG, PMG, and Pin (purity \geq 99%; National Institutes for Food and
81 Drug Control, Beijing, China) were used as the standards (dissolved in methanol) for the structural
82 analysis and product identification. [$^{13}\text{C}_6$]-Labeled phenylalanine and glucose were purchased from the
83 Qingdao TrachinoidCo (\geq 99%; Qingdao, China). The purity of the [$^{13}\text{C}_6$]-labeled Phe and glucose was
84 99%. Methanol (HPLC grade) was purchased from Fisher Scientific (Fairlawn, NJ, USA). The water
85 used in the experiment was purified using a Milli-Q water purification system (18.5 M) (Millipore
86 Corp., Bedford, MA, USA). Other reagents and chemicals were of analytical grade.

87 **Preparation of *Phomopsis* sp. XP-8 cells**

88 *Phomopsis* sp. XP-8 was grown at 28°C on potato dextrose agar plates for 5 days. Then, three
89 pieces of mycelia (5 mm in diameter) were inoculated into 100 mL liquid potato dextrose broth in a
90 250-mL flask and cultivated at 28°C on a rotary shaker (180 rpm). After 4 days, the cells were collected

91 by centrifugation at 4°C (1,136×g for 10 min) using a centrifuge (HC-3018R, Anhui USTC Zonkia
92 Scientific Instruments Co., Ltd., Anhui, China). The cells were washed twice with sterile water and
93 used for bioconversion according to the experimental design.

94 **Bioconversion systems**

95 The bioconversion with normal glucose as the sole substrate was carried out in a 250-mL flask
96 containing 100 mL of ultrapure water (pH 7), 15 g/L glucose, and the prepared *Phomopsis* sp. XP-8 cell
97 set a ratio of 10 g cells (wet weight) per 100 mL medium. To track the mass flow from glucose to PDG,
98 15 g/L glucose was changed to 5 g/L [¹³C₆]-labeled glucose (5 g/L) in the above medium and the same
99 conditions were used for bioconversion.

100 Bioconversion with Phe as the sole substrate was carried out in medium containing 0.15 g/L
101 glucose (used for the glycosyl donors), 7 mM [¹³C₆]-labeled phenylalanine, and the prepared
102 *Phomopsis* sp. XP-8 cells at a ratio of 10 g wet cells per 100 mL medium.

103 All bioconversions were carried out for 48 h at 28°C and 180 rpm. At the end of bioconversion,
104 the broth was collected and filtered through an intermediate speed qualitative filter paper before the
105 products were detected.

106 **Identification of the accumulated products during bioconversion**

107 The products were extracted from the vacuum-evaporated (0.09 MPa, 50°C) bioconversion broth
108 with methanol and adjusted to 4 mL for the UPLC measurements after filtration through a membrane
109 (0.45 μm, 13 mm diameter; Millipore, Billerica, MA, USA). The UPLC analysis was performed on a
110 Waters Acquity UPLC system (Waters Corp., Milford, MA, USA), equipped with a binary pump, a
111 thermostatically controlled column compartment, and a UV detector. Gradient elution was performed
112 on an Acquity UPLC™ BEH C18 column (50 mm × 2.1 mm I.D., 1.7 μm; Waters) and the column
113 temperature was maintained at 30°C, while sample temperature was 10°C (15).

114 The MS analysis of the products was carried out on a Q-TOF Premier™ with an ESI source
115 (Waters Corp.) at the optimized parameters of: capillary voltage, 2.8 kV; sampling cone voltage, 20 V;
116 extractor voltage, 4 V; source temperature, 100°C; desolvation temperature, 250°C, and flow rate of the
117 desolvation gas (N₂), 400 L/h. The collision cell parameters for the Q-TOF-MS/MS analysis were:
118 collision gas (Argon) flow rate, 0.45 L/h; collision energy, 15–35 eV. The mass spectra were recorded
119 using full scan mode over a mass range of m/z 100–800 in negative ion mode. The MS acquisition rate
120 was set to 1.0 s, with a 0.02 s inter-scan delay. The Q-TOF-MS/MS experiments were carried out by

121 setting the quadrupole to allow ions of interest to pass prior to fragmentation in the collision cell.

122 Accurate mass measurements were obtained by means of a lock mass that introduces a low flow
123 rate (3 L/min) of a chrysophanol (253.0499) calibrating solution in the ESI-Q-TOF-MS and
124 ESI-Q-TOF-MS/MS. All operations and acquisition and data analyses were controlled by Masslynx
125 V4.1 software (Waters Corp.).

126 **Data processing**

127 Peak detection, alignment, and identification of the detected compounds were performed using
128 Masslynx V4.1 software (Waters Corp.). The MS/MS fragmentation patterns were used for informative
129 non-targeted metabolic profiling of the LC-MS data, and the acquired LC-MS/MS spectrum was
130 identified after comparison with spectra proposed by the Mass bank database (www.massbank.jp), the
131 KEGG database, and related reports.

132

133 **Results**

134 **Detection of products converted from normal glucose**

135 Production of PDG, monoglucoside (PMG), Pin, Phe, *p*-coumaric acid (*p*-Co), and cinnamic acid
136 (Ca) were detected in bioconversion systems using glucose as the sole substrate. Data in Figs. 2–7
137 show the mass spectra of these compounds accumulated in the bioconversion systems and the
138 corresponding standards.

139 Production of Phe was detected at a molecular weight and major daughter ions of $m/z = 164.08$
140 and $m/z = 147.06$, respectively (Fig. 2D), which was consistent with the data obtained from the
141 corresponding standards (Fig. 2B). Similarly, production of PDG, PMG, Pin, *p*-Co, and CA was also
142 detected in the bioconversion system, indicating that glucose was converted to these products by
143 *Phomopsis* sp. XP-8, as only glucose was provided in the bioconversion system.

144 **Identification of products converted from [¹³C₆]-labeled phenylalanine**

145 The phenylpropane pathway in plants starts with Phe and ends with *p*-Co. The same mass flow
146 was previously detected during production of PDG from glucose by *Phomopsis* sp. XP-8 (Zhang et al.,
147 2015b). To verify this finding and the role of the Phe pathway in the biosynthesis of PDG, PMG, and
148 Pin, [¹³C₆]-labeled Phe was used as the sole substrate in the bioconversion system with 5 g/L glucose

149 (mainly used as the glucoside donor). As results, ^{13}C labeled Pin, Phe, *p*-Co, and Ca were successfully
150 detected (Fig. 8).

151 The retention time (RT) of [$^{13}\text{C}_6$]-labeled Phe was the same as the Phe standard (Figs.2A and 8A).
152 The molecular weight and major daughter ions of [$^{13}\text{C}_6$]-labeled Phe were obtained at $m/z = 170.09$
153 (Fig. 8A), indicating six ^{13}C in Phe. Similarly, the other products were also successfully detected at the
154 same RT of their corresponding normal standard substrates. All ^{13}C -labeled product data and their
155 corresponding standard substrates are summarized in Table 1.

156 Standard Ca ($\text{C}_9\text{H}_8\text{O}_2$) was detected at a RT of 17.94 min with molecular weight and major
157 daughter ions obtained at $m/z = 147.05$ and $m/z = 103.06$, respectively. (Fig. 3A,B). ^{13}C -Labeled Ca
158 was detected in the bioconversion system at a molecular weight of $m/z=153.07$, indicating that six ^{13}C
159 were introduced into Ca (Fig. 8B). The major daughter ions of ^{13}C -labeled Ca were obtained at m/z
160 $=109.08$, indicating six ^{13}C referring to the standard Ca ($m/z=103.06$). The structure of ^{13}C -labeled Ca
161 with out-COOH was the major daughter ion at $m/z=103.06$. Therefore, it was deduced that the six ^{13}C
162 were in a benzene ring not in -COOH.

163 According to the mass spectra of the *p*-Co standard ($\text{C}_9\text{H}_8\text{O}_3$, RT= 5.75min, the molecular weight
164 and major daughter ions were obtained at $m/z = 163.05$ and $m/z = 119.06$ respectively) (Fig. 4A, B).
165 *p*-Co produced in the conversion system was detected at a molecular weight of $m/z= 169.05$ and
166 revealed six ^{13}C by consulting the *p*-Co standard ($m/z= 163.05$). The major daughter ions of
167 ^{13}C -labeled *p*-Co were obtained at $m/z =125.07$, which was six more than that of the *p*-Co standard
168 ($m/z=119.06$). The structure of ^{13}C -labeled *p*-Co without-COOH was detected at the major daughter
169 ion of $m/z=119.06$. Therefore, it was deduced that the six ^{13}C might be distributed in the benzene ring.

170 ^{13}C -Labeled Pin was detected (Fig. 8D-1) and compared with the mass spectra of the Pin standard
171 ($\text{C}_{20}\text{H}_{22}\text{O}_6$, RT= 9.736 min, the molecular weight and major daughter ions were obtained at $m/z =$
172 357.13 and $m/z = 151.04$ respectively) (Fig. 8D-2). The molecular weight of ^{13}C -labeled Pin was
173 identified at $m/z= 369.05$, which was 12 more than that of standard Pin ($m/z= 357.13$). The major
174 daughter ions of ^{13}C -labeled Pin were obtained at $m/z =125.07$, indicating six more than that of the Pin
175 standard ($m/z=151.04$). The structure of ^{13}C -labeled Pin with loss of a benzene ring was identified as
176 the major daughter ion of $m/z=151.04$ (Fig. 7D-1). This result confirmed that the six ^{13}C were
177 distributed in a benzene ring, whereas the other six ^{13}C might be in a symmetrical benzene ring.
178 Therefore, we deduced that the Pin with 12 ^{13}C was bio-converted from the [$^{13}\text{C}_6$]-labeled Phe, Ca,

179 or/and *p*-Co. This finding also confirmed that the benzene ring in Pin came from Phe, which is
180 consistent with that of the lignan biosynthetic pathway in plants.

181 **Identification of products converted from [¹³C₆]-labeled glucose**

182 To explore where Phe originated from the Pin biosynthetic pathway, [¹³C₆]-labeled glucose was
183 supplied as the sole substrate in the bioconversion system with *Phomopsis* sp. XP-8 cells. As results,
184 ¹³C labeled PDG, PMG, Pin, Phe, *p*-Co, and Ca were detected (Fig. 8).The products were detected
185 according to the RTs of the corresponding standards. The detailed information on the products and
186 corresponding standards is shown in Table 2.

187 According to the mass spectra of the Phe (C₉H₁₁NO₂) standard with a RT of 2.06 min, ¹³C labeled
188 Phe was detected in the conversion system with [¹³C₆]-labeled glucose as the sole substrate at a
189 molecular weight of *m/z*=168.06, 169.06, 170.07, 171.07, 172.07, and 173.08 (Fig. 9A), indicating four,
190 five, six, seven, eight, and nine ¹³C in ¹³C-labeled Phe, respectively. This result illustrates that there
191 were four, five, six, seven, eight, and nine carbons in the Phe from glucose. The major daughter ions at
192 *m/z* = 151.04, 107.05, and 108.06 detected in ¹³C-labeled Phe showed that there were four, five, and six
193 ¹³C in Phe, respectively, compared to the daughter ions of the Phe standard (*m/z*= 147.06, *m/z* =
194 103.06). Phe without ¹³C was not detected, indicating that all detected Phe was converted from glucose
195 via the shikimic acid pathway according to KEGG pathway database. The possible positions of ¹³C in
196 Phe are summarized in Table 2.

197 Referring to the mass spectra of the Ca standard (C₉H₈O₂, RT= 17.94 min, molecular weight of
198 *m/z* = 147.05, major daughter ion of *m/z* = 103.06) (Fig. 3A, B), ¹³C-labeled Ca was detected in the
199 bioconversion system with ¹³C₆-labeled glucose as the sole substrate (Fig. 9B). ¹³C-Labeled Ca was
200 detected at *m/z*=147.06, 149.08, 152.09, 153.09, and 154.05, corresponding to zero, two, four, five, and
201 six ¹³C in the detected molecules, respectively, indicating that they were converted from [¹³C₆]-labeled
202 glucose. The major daughter ions of ¹³C-labeled Ca were obtained at *m/z* =108.05, indicating five ¹³C in
203 the molecule compared with that of normal Ca (*m/z*=103.06).Notably, Ca without ¹³C was also detected
204 in the bioconversion system, showing that Ca could also be produced from substrates other than
205 glucose. This was more complex than using Phe as the substrate. The possible positions of ¹³C in Ca
206 are summarized in Table 2.

207 According to the mass spectra of the *p*-Co standard (C₉H₈O₃, RT= 5.75min, molecular weight of

208 $m/z = 163.05$, and major daughter ion of $m/z = 119.06$) (Fig. 4A,B), $^{13}\text{C}_6$ -labeled *p*-Co was detected in
209 the bioconversion system at $m/z=163.05, 168.06, 169.06, 170.07, 171.07, \text{ and } 172.08$ (Fig. 9C).
210 Compared to the molecular weight of the *p*-Co standard ($m/z= 163.05$), the detected ^{13}C -labeled *p*-Co
211 indicated that zero, five, six, seven, eight, and nine carbons in *p*-Co came from ^{13}C -labeled glucose.
212 The *p*-Co with, five, six, seven, eight, and nine ^{13}C may have been converted from [$^{13}\text{C}_6$]-labeled glucose.
213 The major daughter ion of ^{13}C -labeled-Co was detected at $m/z = 119.05$, which was the same as that of
214 the normal *p*-Co standard ($m/z=119.08$). Normal *p*-Co was also detected in the bioconversion system,
215 indicating that *p*-Co could also be formed from substrates other than glucose. The possible positions of
216 ^{13}C in *p*-Co are summarized in Table 2.

217 According to the mass spectra of standard PDG ($\text{C}_{32}\text{H}_{42}\text{O}_{16}$, RT= 5.868 min, molecular weight of
218 $m/z = 681.26$ and major daughter ion of $m/z = 519.19$) (Fig. 5A,B), ^{13}C -labeled PDG was detected at
219 $m/z=695.54, 698.19, 699.27, 700.27, 701.29, 703.25, 704.23, 705.26, 706.25, \text{ and } 707.26$ (Fig. 9D),
220 indicating the occurrence of 14, 17, 18, 19, 20, 21, 22, 23, 24, 25, and 26 ^{13}C in PDG, respectively.
221 Glucose may be the sole glycosyl donor in the biosynthesis of PDG by *Phomopsis* sp. XP-8 (Zhang et
222 al. 2015a, b), so there should be more than 12 ^{13}C in PDG. As expected, more than 14 ^{13}C were
223 detected in ^{13}C -labeled PDG. Therefore, it was confirmed that glucose was the sole glycosyl donor for
224 PDG biosynthesis. The maximum number of ^{13}C was detected in PDG. If the two glycosides of PDG
225 were all ^{13}C , the other 14 ^{13}C would from the C-skeleton of the Pin structure; if all C-skeletons of the
226 Pin structure were formed of ^{13}C , there would be only one ^{13}C -labeled glycoside in PDG. Therefore,
227 glucose not only provided glycoside groups to PDG, but also provided the core Pin structure. The
228 possible positions of ^{13}C in PDG are summarized in Table 2.

229 According to the mass spectra of the PMG standard ($\text{C}_{26}\text{H}_{32}\text{O}_{11}$, RT= 7.597 min, molecular weight
230 of $m/z = 519.20$, and major daughter ion of $m/z = 357.13$) (Fig. 6A,B), ^{13}C -labeled PMG was detected at
231 a molecular weight of $m/z=520.29, 521.26, 522.27, 523.29, 524.29, 526.29, 527.28, 528.28, 529.32,$
232 $530.31, 531.29, 533.21, 535.27, 537.33, 538.29, 541.31, \text{ and } 543.32$ (Fig. 9E), corresponding to 1, 2, 3,
233 4, 5, 7, 8, 9, 10, 11, 12, 14, 16, 18, 19, 22, and 26 ^{13}C in PMG, respectively, compared with that of PMG
234 ($m/z=519.20$). One glycoside is present in the structural formula of PMG. If the glycoside came from
235 glucose, there should be at least six ^{13}C in PMG. The occurrence of a molecule with less than six ^{13}C
236 PMG indicates that the PMG glycoside could have been converted from another substrate, instead of
237 the added [$^{13}\text{C}_6$]-labeled glucose. However, the detection of 26 ^{13}C in PMG illustrates that the PMG

238 glucoside could also be converted from [$^{13}\text{C}_6$]-labeled glucose. The major daughter ions of ^{13}C -labeled
239 PMG were detected at $m/z = 151.04$, $m/z = 357.28$, 359.23 , 361.16 , 362.30 , 364.30 , 365.28 , 366.28 ,
240 367.31 , 368.29 , 370.25 , 374.32 , and 376.30 (Fig. 9E-2), indicating 0, 2, 4, 5, 7, 8, 9, 10, 11, 13, 17, and
241 ^{19}C in PMG, respectively, after a comparison to the PMG standard ($m/z = 357.13$). The major
242 daughter ion of PMG ($m/z = 357.13$) indicated the molecular weight of the core structure of PMG
243 without the glycoside (20 C). This finding indicates that the core structure of PMG may have partly
244 originated from [$^{13}\text{C}_6$]-labeled glucose. The possible positions of ^{13}C in PMG are summarized in Table
245 2.

246 According to the mass spectra of the Pin standard ($\text{C}_{20}\text{H}_{22}\text{O}_6$, $\text{RT} = 9.736$ min, molecular weight of
247 $m/z = 381.1$ and major daughter ion of $m/z = 341.1$)(Fig. 7A,B), ^{13}C -labeled Pin was detected at
248 $m/z = 390.2$, 391.2 , 392.2 , 393.2 , 394.2 , 396.2 , and 397.2 (Fig. 9F), indicating 9, 10, 11, 12, 13, 15, and
249 ^{16}C in the detected Pin, respectively, compared with the Pin standard ($m/z = 381.1$). There are 20 C in
250 the molecular formula of Pin ($\text{C}_{20}\text{H}_{22}\text{O}_6$). The maximum of ^{16}C was detected in the formed Pin,
251 indicating the [$^{13}\text{C}_6$]-labeled glucose partly contributed to the formation of Pin. The major daughter
252 ions of ^{13}C -labeled Pin were detected at $m/z = 346.2$, 347.2 , 349.2 , 350.2 , and 356.2 (Fig. 9F-2),
253 indicating 5, 6, 8, 10, and 15 ^{13}C in the detected Pin, respectively, compared with the Pin standard
254 ($m/z = 341.1$). This finding illustrates that the core Pin structure was partly converted
255 from [$^{13}\text{C}_6$]-labeled glucose. The possible positions of ^{13}C in Pin are summarized in Table 2.

256 Taken together, the possible biosynthetic pathways for PDG, PMG, and Pin are summarized in Fig.
257 10. The mass flow from [$^{13}\text{C}_6$]-Phe to [$^{13}\text{C}_6$]-Ca, [$^{13}\text{C}_6$]-*p*-Co, and [$^{13}\text{C}_{12}$]-Pin was verified by the
258 experiments using [$^{13}\text{C}_6$]-labeled Phe as the sole substrate. The mass flow from [$^{13}\text{C}_6$]-glucose
259 to [$^{13}\text{C}_6$]-Phe, [$^{13}\text{C}_6$]-Ca, [$^{13}\text{C}_6$]-*p*-Co, [$^{13}\text{C}_{12}$]-Pin, [$^{13}\text{C}_{18}$]-PMG, and [$^{13}\text{C}_{24}$]-PDG was verified by the
260 data obtained using [$^{13}\text{C}_6$]-glucose as the sole substrate (Fig. 10A).

261 Possible pathways for biosynthesis of PDG and PMG

262 Two structures of PMG were detected: one was [$^{13}\text{C}_{12}$]-PMG with two benzene rings converted
263 from ^{13}C -labeled glucose and a normal glycoside (M, $m/z 531.29$), and the other was [$^{13}\text{C}_{18}$]-PMG with
264 both benzene ring structures converted and a glucoside from ^{13}C -labeled glucose (M1, $m/z 537.33$).
265 Similarly, two PDG structures were detected: one was [$^{13}\text{C}_{18}$]-PDG with a two benzene ring structure
266 and one glycoside converted from ^{13}C -labeled glucose (D1, $m/z 699.27$); the other one was [$^{13}\text{C}_{24}$]-

267 PDG with two benzene rings and two glycosides from ^{13}C -labeled glucose (D2, m/z 705.26).

268 If PMG was the direct precursor of PDG, M would be converted to D1 by bonding one
269 [$^{13}\text{C}_6$]-labeled glycoside through glycosylation; M1 could be converted to D1 by bonding one normal
270 glycoside through glycosylation and to D2 by bonding one [$^{13}\text{C}_6$]-labeled glycoside. If this is true, D1
271 would have two glucoside sources, whereas D2 would have only one glucoside source. Therefore, the
272 concentration of D2 should be lower than D1. However, the data show that the relative abundance of
273 D2 (m/z=705) was much higher than that of D1 (m/z=699). Therefore, PMG was not the precursor of
274 PDG.

275 In contrast, if PDG was the direct precursor of PMG, D1 would be converted to M by
276 hydrolyzation of one [$^{13}\text{C}_6$]-labeled glycoside and to M1 by hydrolyzation of one normal glycoside; D2
277 would be converted to M1 by hydrolyzation of one [$^{13}\text{C}_6$]-labeled glycoside. If this is true, M1 would
278 have two glycoside sources, where as M would have only one source. The concentration of M should
279 be lower than M1. However, the data show that relative abundance of M (m/z = 531.29) was higher
280 than that of M1 (m/z=699). Therefore, PDG was not the precursor of PMG.

281

282 **Discussion**

283 The ^{13}C stable isotope labeling method was successfully used in this study to verify the
284 phenylpropanoid-pinoresinol and biosynthetic pathway its glycosides in *Phomopsis* sp. XP-8 during
285 mass flow. It was very important to verify the occurrence of this pathway in microorganisms for the
286 first time. Stable-assisted metabolomics are an efficient way to trace and identify bio-transformed
287 products and the metabolic pathways involved in their formation, such as understanding the fate of
288 organic pollutants in environmental samples (19). This is the first time that this method has been used
289 to verify the occurrence of phenylpropanoids in a microorganism. Compared with previous studies
290 using precursor feeding, detection of enzyme activity, and genomic annotation, this is the first time this
291 pathway has been illustrated by credible visual evidence. More importantly, it is the first time that
292 differences between the PDG and PMG biosynthetic pathways have been verified.

293 The results obtained in this study verify the existence of the phenylpropanoid-lignan metabolic
294 pathway in *Phomopsis* sp. XP-8. Genomic annotation is an efficient way to discover the pathways that
295 are normally difficult to reveal by metabolic and enzymatic evidence due to low intermediate
296 accumulation, low end-product production, and silent gene expression under normal conditions. This

297 method has been successfully used to identify the existence of a phenylpropanoid metabolic pathway in
298 *Aspergillus oryzae* (28), and the molecular genetics of naringenin biosynthesis, a typical plant
299 secondary metabolite in *Streptomyces clavuligerus*(29), and the occurrence of the
300 phenylpropanoid-lignan pathway in *Phomopsis* sp. XP-8 (17). However, further evidence is still needed
301 to verify gene functions and identify the key metabolites. This study reports the existence of
302 thephenylpropanoid-lignan pathway *Phomopsis* sp. XP-8during mass flow and identified the
303 metabolites. Further studies are still needed to verify the gene functions.

304 Additional studies should illustrate the origin of the genes in the phenylpropanoid-lignan pathway
305 of *Phomopsis* sp. XP-8. Horizontal gene transfer (HGT) has long been recognized as an important force
306 in the evolution of organisms (30). HGT occurs among different bacteria and plays important roles in
307 the adaptation of microorganisms to different hosts or environmental conditions (31). More and more
308 evidence for gene transfer between distantly related eukaryotic groups has been presented
309 (30).Therefore, we cannot exclude the possibility that XP-8 may have acquired the genes related to the
310 lignan biosynthetic pathway from its host plant by HGT during long-term symbiosis and evolution.
311 However, further evidence is still needed to verify this proposed process.

312 The results obtained in this study provide useful information on the biosynthesis of lignans and
313 their glycosides via microbial fermentation. Biosynthesis of lignans is of great interest to organic
314 chemists as it provides a model for biomimetic chemistry and has extensive applications
315 (32).Improvement shave been made in the techniques to biosynthesize lignan products by regulating
316 the lignan biosynthetic pathway in trees through genetic modifications (33).However, the lignan
317 biosynthetic pathway has rarely been reported. More importantly, the bioconversion sequence from Pin
318 to PDG and the direct precursor of PDG have remained unclear until now. In previous studies on
319 *Phomopsis* sp. XP-8, the highest production of PDG and PMG did not occur simultaneously (14) and
320 PMG was not the precursor of PDG because PDG production decreased and/or disappeared when PMG
321 yield increased (15). The present study demonstrated that PMG was not the precursor of PDG, and
322 PDG was not the precursor of PMG, indicating that Pin might be converted to PMG and PDG via two
323 different pathways in *Phomopsis* sp. XP-8, which has not been revealed in plants.

324 Furthermore, this study revealed that the bioconversion of Pin, PMG, and PDG from glucose
325 occurred simultaneously as that from Phe. We found that the benzene ring structure of Phe did not open
326 throughout the entire Pin bioconversion process in *Phomopsis* sp. XP-8 when Phe was used as the sole

327 substrate, indicating that the Pin benzene ring originated from Phe. Glucose was converted to Phe and
328 was the sole glycoside donor for PDG biosynthesis. Therefore, glucose not only participated in the
329 formation of glycosides in PDG, but also provided the PDG benzene ring structure. This is different
330 from that found in plants, indicating there might be some other different pathways to produce these
331 products in *Phomopsis* sp. XP-8.

332 Not all intermediates in the KEGG-identified plant-lignan biosynthetic pathway related to Pin,
333 PMG, and PDG formation were found in *Phomopsis* sp. XP-8, such as caffeic acid, ferulic acid, and
334 coniferyl alcohol (Fig. 1). This may be because the pathways after *p*-Co are different in XP-8 from
335 those in plants, or the accumulation of these intermediates was too less to be detected. Further studies
336 are needed to verify this hypothesis.

337 **Conclusion**

338 In summary, the mass flow of the Pin, PMG, and PDG biosynthetic pathway in *Phomopsis* sp.
339 XP-8 was verified as the following: starting from [$^{13}\text{C}_6$]-Phe to [$^{13}\text{C}_6$]-Ca, [$^{13}\text{C}_6$]-*p*-Co, and [$^{13}\text{C}_{12}$]-Pin
340 when there was only Phe as the sole substrate; starting from [$^{13}\text{C}_6$]-glucose to [$^{13}\text{C}_6$]-Phe, [$^{13}\text{C}_6$]-Ca,
341 [$^{13}\text{C}_6$]-*p*-Co, [$^{13}\text{C}_{12}$]-Pin, [$^{13}\text{C}_{18}$]-PMG, and [$^{13}\text{C}_{24}$]-PDG when there was high level of glucose (15 g/L)
342 as the sole substrate (Fig. 10A).
