Running title: A piRNA locus required for fertility

SUMMARY ( $\leq 150$ words; now 150)

Pachytene piRNAs, which comprise $>80 \%$ of all small RNAs in the adult mouse testis, have been proposed to bind and regulate target RNAs like miRNAs, to cleave targets like siRNAs, or to lack biological function altogether. Although mutants lacking proteins that make pachytene piRNAs are male sterile, no biological function has been identified for any mammalian piRNA-producing locus. Here, we report that loss of piRNA precursor transcription from a conserved pachytene piRNA locus on mouse chromosome 6 (pi6) perturbs male fertility. Loss of pi6 piRNAs has no measurable effect on sperm quantity or transposon repression, yet pi6 $6^{-/-}$mice produce sperm with defects in motility, egg fertilization, and embryo development, severely reducing pup production even at the peak of male reproduction. Our data establish a direct role for pachytene piRNAs in spermiogenesis and embryo viability and enable new strategies to identify the RNA targets of individual piRNA species.

Keywords: PIWI-interacting RNA; piRNA; MIWI; A-MYB; MYBL1, spermatogenesis; acrosome; zona pellucida; sperm; pachytene piRNA; meiosis

## Highlights

- Normal male mouse fertility and spermiogenesis require piRNAs from the pi6 locus
- Normal sperm motility and binding to zona pellucida require pi6 piRNAs
- Sperm from pi6 males fail to support embryo development
- Defects in pi6 sperm reflect changes in the abundance of specific mRNAs

## INTRODUCTION

Only animals produce PIWI-interacting RNAs (piRNAs), 21-35-nt small RNAs that form the most abundant class of small RNA in the germline. In most animals, piRNAs protect the germline genome from transposons and repetitive sequences, and, in many arthropods, piRNAs fight viruses and transposons in somatic tissues (Houwing et al., 2007; Aravin et al., 2008; Batista et al., 2008; Das et al., 2008; Lewis et al., 2018). The mammalian male germline makes three classes of piRNAs: (1) 26-28 nt transposonsilencing piRNAs predominate in the fetal testis (Aravin et al., 2008); (2) shortly after birth 26-27 nt piRNAs derived from mRNA 3' untranslated regions (UTRs) emerge (Robine et al., 2009); and (3) at the pachytene stage of meiosis, $\sim 30 \mathrm{nt}$, non-repetitive pachytene piRNAs appear. Pachytene piRNAs accumulate to comprise $>80 \%$ of all small RNAs in the adult mouse testis, and they continue to be made throughout the male mouse reproductive lifespan. These piRNAs contain fewer transposon sequences than the genome as a whole, and most pachytene piRNAs map only to the loci from which they are produced. The diversity of pachytene piRNAs is unparalleled in development, with >1 million distinct species routinely detected in spermatocytes or spermatids. Intriguingly, the sequences of pachytene piRNAs are not themselves conserved, but piRNA-producing loci have been maintained at the syntenic regions across eutherian mammals (Girard et al., 2006; Chirn et al., 2015), suggesting that the vast sequence diversity of pachytene piRNAs is itself biologically meaningful.

In mice, 100 pachytene piRNA-producing loci have been annotated (Girard et al., 2006; Grivna et al., 2006; Lau et al., 2006; Ro et al., 2007; Li et al., 2013). All are coordinately regulated by the transcription factor A-MYB (MYBL1), which also promotes expression of proteins that convert piRNA precursor transcripts into mature piRNAs, as well as proteins required for cell cycle progression and meiosis (Bolcun-Filas et al., 2011). Of the 100 piRNA-producing loci, 15 pairs of pachytene piRNA-producing genes
are divergently transcribed from bidirectional, A-MYB-binding promoters (Li et al., 2013). The contribution of pachytene piRNAs from each piRNA-producing locus is unequal, with just five loci-pi2, pi6, pi7, pi9, and pi17—contributing to $>50 \%$ of all pachytene piRNA production at 17 days postpartum (dpp).

Loss of proteins required to make pachytene piRNAs, including the pachytene piRNA-binding protein, MIWI (PIWIL1), invariably arrests spermatogenesis and renders males sterile (Deng and Lin, 2002; Reuter et al., 2011; Zheng and Wang, 2012; Li et al., 2013; Castañeda et al., 2014; Wasik et al., 2015). Yet, loss of the chromosome 17 pachytene piRNA-producing locus, 17-qA3.3-27363(-),26735(+) (henceforth, pi17), has no detectable phenotype or impact on male fertility (Homolka et al., 2015), even though pi17 produces $\sim 30 \%$ of all pachytene piRNAs. Similarly, mice disrupted in expression of a piRNA cluster on chromosome 2 are viable and fertile (P.-H.W., K.C., and PDZ, unpublished; Xu et al., 2008). Consequently, the function of pachytene piRNAs in mice is actively debated. One model proposes that pachytene piRNAs regulate meiotic progression of spermatocytes by cleaving mRNAs during meiosis (Goh et al., 2015; Zhang et al., 2015). Another model posits that pachytene piRNAs direct degradation of specific mRNAs via a miRNA-like mechanism involving mRNA deadenylation (Gou et al., 2014). A third model proposes that MIWI functions without piRNAs, and that piRNAs are byproducts without a critical function (Vourekas et al., 2012). Compelling evidence exists to support each model.

In fact, direct demonstration of piRNA function in any animal has proven elusive. Only two piRNA-producing loci have been directly shown to have a biological functionboth are in flies and were identified genetically before the discovery of piRNAs (Livak, 1984; Livak, 1990; Palumbo et al., 1994; Pélisson et al., 1994; Bozzetti et al., 1995; Prud'homme et al., 1995; Robert et al., 2001; Robert et al., 2001; Mével-Ninio et al., 2007). In male flies, piRNAs from Suppressor of Stellate, a multi-copy gene on the $Y$ chromosome, silence the selfish gene Stellate, and deletion of Suppressor of Stellate
leads to Stellate protein crystals in spermatocytes (Aravin et al., 2001; Aravin et al., 2003). In female flies, deletion of the piRNA-producing flamenco gene, which is expressed in somatic follicle cells that support oogenesis, leads to gypsy family transposon expression and infertility (Brennecke et al., 2007; Saito et al., 2009).

Here, we report that a small promoter deletion in the chromosome 6 pachytene piRNA cluster 6-qF3-28913(-), 8009(+) (henceforth, pi6) that eliminates pi6 piRNA production disrupts male fertility. The pi6 locus, one of the five most productive piRNAproducing loci in mice, generates $5.8 \%$ of pachytene piRNAs in the adult testis and is conserved among eutherian mammals. Mice lacking pi6-derived piRNAs produce normal numbers of sperm and continue to repress transposons. However, pi6 mutant sperm fertilize eggs poorly due to defective sperm motility and zona pellucida penetration. Consistent with these phenotypes, the steady-state abundance of mRNAs encoding proteins crucial for cilial function, zona pellucida proteolysis, and egg binding was significantly decreased in sperm progenitor cells from pi6 males. Our findings provide direct evidence for a biological function for pachytene piRNAs in male mouse fertility, and pi6 promoter deletions provide a new model for the future identification of piRNA targets in vivo.

## RESULTS

## pi6 Promoter Deletion Eliminates pi6 pachytene piRNAs

To eliminate production of pi6 pachytene piRNAs while minimizing the impact on adjacent genes, we used a pair of single-guide RNAs to delete 227 bp , including the A-MYB-binding promoter sequences, from pi6 (Figure 1, S1A, and S1B, and Table S1; Li et al., 2013). For comparison, we created an analogous promoter deletion in pi17. We established stable mutant lines (pi6 ${ }^{e m 1}-1,-2$, and -3 in Figure S1B) from three founders whose pi6 promoter deletion sizes range from 219 to 230 bp and differ at their deletion boundaries, reflecting imprecise DNA repair after Cas9 cleavage. All three deletions
eliminated pi6 primary transcripts and mature pachytene piRNAs from both arms of the locus (Figure 1). Because these lines were created using the same pair of sgRNA guides, we refer to all as the pi $6^{\text {em1 }}$ allele.

## pi6 is Required for Male Mouse Fertility

When paired with C57BL/6 females, pi6 ${ }^{\text {em1/em1 }}$ males between 2 and 8 months old produced fewer pups compared to their littermates, even at peak reproductive age (Figure 2A and S2A). In six months, C57BL/6 males produced $7 \pm 1(n=5)$ litters, while pi6 ${ }^{\text {em1/em1 }}$ males produced $2 \pm 2(n=6)$ litters. The significantly smaller number of progeny produced by pi6 ${ }^{\text {em1/em1 }}$ males over their reproductive lifetime does not reflect fewer pups produced in each litter: pi6 ${ }^{e m 1 / \mathrm{m} 1}$ males sired $5 \pm 2(n=4)$ pups per litter compared to $6 \pm 2(n=27)$ pups per litter for C57BL/6 control males (Figure 2A). Moreover, pi6 ${ }^{\text {em1/em1 }}$ males regularly produced mating plugs, a sign of mating, in cohabiting females. Instead, the reduced progeny from pi6 ${ }^{\mathrm{em1/em} 1}$ males reflects two abnormal aspects of their fertility (Figure 2B). First, 29\% of pi6 ${ }^{\mathrm{em} 1 / \mathrm{em1}}$ males never produced pups. Second, the mutants that did sire pups did so less frequently. These defects are specific for the loss of pi6 piRNAs in males, because pi6/em1 heterozygous males and pi6 em1/em1 homozygous mutant females showed no discernable phenotype. As observed previously for a partial-loss-of-function pi17 promoter deletion (Homolka et al., 2015), males and females carrying a $\sim 583$-bp promoter deletion in pi17 were fully fertile, despite loss of primary transcripts and mature piRNAs from both arms of the pi17 locus (Figure 1).

To test that the reduced fertility of pi6 $6^{e m 1 / e m 1}$ male mice reflects loss of the pi6 promoter-and not an undetected Cas9-induced off-target mutation elsewhere in the genome-we used Cas9 and a second pair of sgRNAs to generate a 117 bp pi6 promoter deletion, pi6em2 (Figures 1, S1A, and S1C, and Table S1). Like pi6 ${ }^{e m 1 / e m 1}$ male mice, pi6 ${ }^{\text {em2/em2 }}$ males produced neither primary pi6 transcripts nor mature pi6 piRNAs
and showed reduced fertility (Figure S2A). We conclude that pi6 piRNAs are required for C57BL/6 male fertility in mice.

## pi6 ${ }^{\text {em1/em1 }}$ Males Produce Fewer Embryos

pi6 mutant male matings were less likely to produce fully developed embryos. We examined the embryos produced by natural mating of C57BL/6 females housed with C57BL/6, pi6 ${ }^{+/ e m 1}$, or pi6 $6^{\text {em1/em1 }}$ males at $8.5,14.5$, or 16.5 days after occurrence of a mating plug. At 8.5 days after mating, C57BL/6 females housed with pi6 $6^{\mathrm{em} 1 / \mathrm{em} 1}$ males carried fewer embryos $(2 \pm 2, n=3)$ compared to the females paired with pi6 $6^{+e m 1}(6 \pm 5$, $n=2$ ) or C57BL/6 control ( $7 \pm 4, n=1$ ) males (Figure 2C). At 14.5 and 16.5 days postmating, female mice paired with pi6 ${ }^{e m 1 / e m 1}$ males had even fewer embryos. Consistent with the observation that naturally-born pups sired by pi6 ${ }^{e m 1 / e m 1}$ males were rare but healthy, the surviving embryos resulting from natural mating showed no obvious abnormalities.

Moreover, pi6 piRNAs appear to play little if any role in the soma of the developing embryo. $p i 6^{+/ e m 1}$ heterozygous males mated to pi6 $6^{+e m 1}$ heterozygous females yielded progeny at the expected Mendelian and sex ratios. Moreover, the weight of pi6 ${ }^{\text {em1/em1 }}$ homozygous pups ( $28.3 \pm 0.6 \mathrm{~g}, n=8$ ) that developed to adulthood was indistinguishable from their C57BL/6 $(26.9 \pm 0.3 \mathrm{~g}, n=8)$ or heterozygous littermates ( $28.6 \pm 0.3 \mathrm{~g}, n=8$ ) (Figure S2B). We detected no difference in the gross appearance or obvious changes in behavior among these pups.

## pi6 ${ }^{\text {em1/em1 }}$ Males Produce Mature Spermatozoa

Two-to-four months after birth, both pi6 $6^{+e m 1}$ and pi6 em1/em1 testes weighed slightly less than C57BL/6 testes (Figure S2B). Nonetheless, pi6 ${ }^{e m 1 / e m 1}$ testis gross histology was normal, with all expected germ cell types present in seminiferous tubules and sperm clearly visible in the lumen (Figure 2D). The quantity of caudal epididymal sperm
produced by pi $6^{\text {em1/em1 }}$ mice ( $19 \pm 10$ million sperm per $\mathrm{ml} ; n=6$ ) was also comparable to that of their pi6 ${ }^{+/ e m 1}(23 \pm 7$ million sperm $/ \mathrm{ml} ; n=4)$ or C57BL/6 $(20 \pm 10$ million sperm per ml; $n=13$ ) littermates (Figure 2E).

Although pi6 ${ }^{\text {em1/em1 }}$ mice produce normal numbers of sperm, the sperm showed signs of agglutination compared to C57BL/6 sperm after 90 min of incubation in vitro, and $\sim 10 \%$ of pi6 ${ }^{\text {em1/em1 }}$ caudal epidydimal sperm had abnormal head morphology (Figure S2C). Defects in germ cell chromosomal synapsis, triggering errors in gene expression, have been linked to abnormal sperm head shape (Wong et al., 2008; de Boer et al., 2015). In fact, $22 \pm 7$ percent of pi6 ${ }^{\mathrm{em1/em} 1}$ pachytene spermatocytes had unsynapsed sex chromosomes or incompletely synapsed autosomal chromosomes, compared to $7 \pm 3$ percent for C57BL/6 $(n=4)$ (Figure S2E).

## pi6 ${ }^{\mathrm{em} 1 / \mathrm{m} 1}$ Sperm Fail to Fertilize

pi6 mutant males produce ordinary numbers of normally shaped sperm ( $\sim 90 \%$ ), yet are ineffectual at siring offspring. We used in vitro fertilization (IVF) to distinguish between defects in mating behavior and sperm function, incubating sperm from C57BL/6, pi6 $6^{+/ e m 1}$, or pi6 $6^{m 1 / e m 1}$ males with wild-type oocytes and scoring for the presence of both male and female pronuclei and the subsequent development of the resulting bipronuclear zygotes into two-cell embryos 24 h later (Figure 3A). The majority of oocytes incubated with C57BL/6 (91 $\pm 5 \%$; $n=5$ ) or pi6 ${ }^{+/ e m 1}(60 \pm 35 \%$; $n=3)$ sperm developed into two-cell embryos. By contrast, only $7 \pm 5 \%(n=7)$ of oocytes incubated with pi $6^{e m 1 / e m 1}$ sperm reached the two-cell stage. The majority of these oocytes remained one-cell embryos, and few contained a male pronucleus, suggesting that pi6em1/em1 sperm are defective in fertilization.

## pi6 ${ }^{\text {em1/em1 }}$ Sperm Nuclei Support Fertilization

The best studied piRNA function is transposon silencing, and mouse pi2 has been proposed to be involved in LINE1 element silencing, although pi2 mutant males are fertile (Xu et al., 2008). Moreover, LINE1 transcript abundance increases in mice bearing inactivating mutations in the catalytic site of MIWI (Reuter et al., 2011). Transposon activation can produce DNA damage, and genomic integrity is critical for fertilization (Ahmadi and Ng, 1999; Morris et al., 2002; Bourc'his and Bestor, 2004; Lewis and Aitken, 2005). However, pachytene piRNAs are depleted of repetitive sequences in contrast to other types of piRNA-producing genomic loci (Figure S3A; Aravin et al., 2006; Girard et al., 2006; Gainetdinov et al., 2018).

We asked whether the defect in fertilization by pi6 $6^{\text {m1/em1 }}$ might reflect DNA damage or epigenetic dysregulation of the pi6 ${ }^{e m 1 / e m 1}$ sperm genome. pi6 $6^{+/ e m 1}$ or pi6em1/em1 sperm heads were individually injected into the cytoplasm of wild-type oocytes (intracytoplasmic sperm injection, or ICSI) (Figure 3B), bypassing the requirement for sperm motility, acrosome reaction, egg binding, or sperm-egg membrane fusion (Kuretake et al., 1996). pi6em1/em1 sperm heads delivered by ICSI fertilized the oocyte at a rate similar to that of pi6 $6^{+/ e m 1}$ sperm: $66 \%$ of oocytes injected with homozygous mutant pi6 $6^{e m 1 / e m 1}$ sperm heads reached the two-cell stage, compared to $79 \%$ for $p i 6^{+/ e m 1}$. Thus, most pi6 ${ }^{\text {em1/em1 }}$ nuclei are capable of fertilization.

The steady-state abundance of transposon RNA in pi6em1/em1 testicular germ cells further supports the view that the fertilization defect caused by loss of pi6 piRNAs does not reflect a failure to silence transposons. We used RNA-seq to measure the abundance of RNA from 1,007 transposons in four distinct germ cell types, purified by fluorescence-activated cell sorting: pachytene spermatocytes (4C), diplotene spermatocytes (4C), secondary spermatocytes (2C), and spermatids (1C). pi6 piRNAs are plentiful in pachytene spermatocytes onwards (Figure S3B), yet when pi6 piRNAs
were eliminated, we found no significant changes in steady-state RNA abundance (i.e., an increase or decrease $\geq 2$-fold and FDR $\leq 0.05$ ) for any transposon family compared to C57BL/6 cells (Figure S3C). We also note that, similar to C57BL/6 testis, $\gamma \mathrm{H} 2 \mathrm{AX}$ expression is confined to meiotic spermatocytes in pi6 ${ }^{\mathrm{em} 1 / \mathrm{em} 1}$ testis, indicating absence of DNA damage (data not shown). Together with the rescue of the fertilization defects of pi6 ${ }^{\text {em1/em1 }}$ sperm by ICSI, these data suggest that transposon silencing is unlikely to be the biological function of pi6 piRNAs.

## Impaired Motility in pi6 Mutant Sperm

To assess whether abnormal sperm motility might contribute to pi6 ${ }^{\text {em1/em1 }}$ male subfertility, we observed freshly extracted caudal epididymal sperm from pi6 ${ }^{\text {em1/em1 }}$ or C57BL/6 mice for 5 h . Ten minutes after sperm extraction, most pi $6^{e m 1 / e m 1}$ sperm moved more slowly than C57BL/6 control sperm (Movies S1 and S2). With time, pi6em1/em1 sperm motility declined more rapidly than C57BL/6 sperm (Movies S3-S10). At 4 and 5 h , most pi6em1/em1 sperm only moved in place and showed signs of agglutination (Movies S8 and S10).

To quantify the differences between pi6 mutant and control sperm, we used computer-assisted sperm analysis (CASA) to measure pi6em2/em2 sperm motility 10 min after isolation (Mortimer, 2000). While control sperm swam at a path velocity comparable to previously reported ( $110 \pm 50 \mu \mathrm{~m} / \mathrm{sec}$ for $221 \pm 75$ cells measured; $n=3$; Ren et al., 2001), pi $6^{\text {em2/em2 }}$ sperm moved at a lower average path velocity $(80 \pm 60 \mu \mathrm{~m} / \mathrm{sec}$ for $232 \pm 57$ cells measured; $n=3)($ Table 1). Similarly, The pi6em2/em2 sperm also showed less forward, progressive movement (progressive velocity = $50 \pm 60 \mu \mathrm{~m} / \mathrm{sec}$ for $232 \pm 57$ cells measured; $n=3$ ) compared to control sperm (progressive velocity $=70 \pm 50 \mu \mathrm{~m} / \mathrm{sec}$ for $221 \pm 75$ cells measured; $n=3$ ). For comparison, knockout of CatSper1 leads to $\sim 65 \%$ reduction in path velocity and $\sim 62 \%$ reduction in progressive velocity (Ren et al., 2001). As a population, the speed and
progressivity of pi6 mutant sperm motility patterns varied more widely than control sperm (Movies S1-S10 and Table 1). Lower average path and progressive velocity in sperm populations is linked to worse outcomes in fertilization and pregnancy in IVF (Donnelly et al., 1998). Thus, the slower and less progressive movement in pi6em1/em1 sperm likely contributes to the subfertility of pi6 ${ }^{e m 1 / e m 1}$ males.

## pi6 Mutant Sperm Struggle to Penetrate the Zona Pellucida

Mammalian spermatozoa stored in the epididymis are dormant. Sperm "capacitate," i.e., resume maturation, only upon entering the female reproductive tract (de Lamirande et al., 1997). Upon capacitation, sperm become capable of undergoing the acrosome reaction, which is required to bind and penetrate the outer oocyte glycoprotein layer, the zona pellucida (Florman and Storey, 1982; de Lamirande et al., 1997; Jin et al., 2011). To test whether the defect in fertilization by pi6 mutant sperm was due to impaired binding to or penetration of zona pellucida, we compared IVF using wild-type oocytes with their zona pellucida either intact or removed (Figure 4A). As before, $10 \pm 6 \%(n=3)$ of intact oocytes incubated with pi6 ${ }^{e m 1 / e m 1}$ sperm reached the two-cell stage, compared to $94 \pm 5 \%(n=3)$ for C57BL/6 sperm (Figure 4B). Strikingly, removing the zona pellucida from the wild-type oocytes fully rescued the fertilization rate of pi6 mutant sperm: $92 \pm 7 \%(n=3)$ of zona pellucida-free oocytes incubated with pi6 ${ }^{\text {em1/em1 }}$ sperm reached the two-cell stage, compared to those with intact zona pellucida ( $10 \pm 6 \% ; n=$ 3)

Ex vivo, the acrosome reaction occurs spontaneously in some sperm and can be further triggered by inducing $\mathrm{Ca}^{2+}$ influx using the ionophore A23187 (Talbot et al., 1976), which results in an acrosome reaction visually indistinguishable from that triggered by natural ligands such as progesterone (Osman et al., 1989) or ZP3 (Arnoult et al., 1996), while bypassing signaling pathways essential for acrosome reaction in vivo (Tateno et al., 2013) (Figure 4C and 4D). The spontaneous acrosome reaction rates for

C57BL/6 (19 $\pm 3 \% ; n=3)$ and pi6 mutant sperm were similar (17 $\pm 8 \% ; n=3$ ). Acrosome reaction triggered by ionophore-induced $\mathrm{Ca}^{2+}$ influx differed between the two genotypes: $45 \pm 14 \%$ of pi6 mutant sperm $(n=3)$ underwent partial or complete reaction, compared to $66 \pm 6 \%(n=3)$ for C57BL/6 (Figure 4C). Our data suggest that pi6 mutant sperm less effectively undergo an acrosome reaction triggered by ionophoreinduced $\mathrm{Ca}^{2+}$ influx, a defect expected to impair binding and penetrating the zona pellucida.

## Potential Role of Paternal pi6 piRNAs in Embryo Development

Even when pi6 sperm successfully fertilize the oocyte, the resulting heterozygous embryos are less likely to complete gestation. Two-cell embryos generated by IVF using heterozygous or homozygous pi6 mutant or C57BL/6 control sperm were transferred to C57BL/6 surrogate mothers (Figure 5A). At least half of embryos from pi6+em1 ( $50 \pm 10 \%$; $n=3$ ) or C57BL6 control ( $70 \pm 10 \%$; $n=3$ ) sperm developed to term (Figure 5B), a rate typical for the C57BL/6 background (González-Jara et al., 2017).

The low number of fertilized two-cell embryos produced in IVF using pi6em1/em1 sperm precluded transferring the standard number of embryos to surrogate mothers. For example, in two IVF experiments using pi6em1/em1 sperm, only 5 or 7 embryos could be transferred; the surrogate females failed to become pregnant (Figure 5B and S4A, Trials 1 and 2). In theory, this result might suggest a paternal role for pi6. A more mundane explanation is that the low number of embryos transferred reduced the yield of live fetuses, as reported previously (McLaren , 1955; Johnson et al., 1996; GonzálezJara et al., 2017). We conducted additional experiments to distinguish between these two possibilities. Oocytes were again fertilized by IVF with pi6 ${ }^{\text {em1/em1 }}$ or C57BL/6 control sperm, and two-cell embryos transferred to surrogate females, but matching the number of embryos transferred to each surrogate for the two sperm genotypes. We used two strategies. First, similar numbers of embryos derived from pi6 ${ }^{\text {em1/em1 }}$ sperm and filler
embryos derived from control sperm were transferred to separate oviducts (Figure 5B, Trials 3 and 4). Again, fewer embryos developed to term for pi $6^{\text {em1/em1 }}$ (17\%) compared to control sperm ( $37 \%$ ). Second, embryos were mixed before transfer and then equal numbers of embryos, selected randomly, were implanted in each oviduct (Figure 5B, Trial 5). Pups isolated by cesarean section 18.5 days after transfer were genotyped by PCR. In this experiment, only $40 \%$ of embryos derived from pi $6^{\text {em1/em1 }}$ sperm developed to term, compared to $80 \%$ of filler embryos. Finally, in one experiment (Trial 6) where we obtained sufficient numbers of embryos derived from pi6 ${ }^{\mathrm{em} 1 / \mathrm{em1}}$ sperm, 10 pi6 ${ }^{\mathrm{em} 1 / \mathrm{em} 1-}$ derived two-cell embryos were transferred to each oviduct of the surrogate female. Nevertheless, only $15 \%$ of the pi6em1/em1-derived embryos developed to term, compared to $85 \%$ of the control.

We also monitored pre-implantation development ex vivo for up to 96 h , a period during which the one-cell embryo develops into a blastocyst. Of all the oocytes incubated with pi $6^{\text {em1/em1 }}$ sperm, $40 \%$ remained one cell without evidence of a male pronucleus, presumably because they were not fertilized by pi $6^{\text {em1/em1 }}$ mutant sperm. Among the remaining $60 \%$ oocytes that progressed to at least two-cell stage, which indicated successfully fertilization by pi6 ${ }^{-m 1 / e m 1}$ sperm, $82 \%$ showed delayed development, requiring 48 h to reach the two-cell stage. None of these developed further. Only $3 \%$ of fertilized oocytes progressed to the blastocyst stage by 96 h , compared to $98 \%$ of oocytes fertilized by C57BL/6 sperm (Figure 5C).

Further support for this idea comes from transfer of embryos generated by ICSI (Figure 5D). ICSI with pi6 ${ }^{\text {em1/em1 }}$ or pi6 $6^{+e m 1}$ sperm yielded comparable normal numbers of fertilized oocytes (Figure 3B), so no filler embryos were used; all embryos were transferred into a single oviduct of the surrogate female. In two independent experiments in which embryos generated by ICSI were transferred to surrogate mothers, only $19 \%$ of two-cell embryos derived from pi $6^{-m 1 / e m 1}$ sperm heads developed to term, compared to $34 \%$ for embryos fertilized with pi6 ${ }^{+/ e m 1}$ (Figure 5C). Only four of
seven (57\%) surrogate mothers carrying embryos derived from pi6em1/em1 sperm became pregnant. All three surrogate mothers receiving embryos derived from pi6 ${ }^{+/ e m 1}$ sperm became pregnant (Figure S4B).

We note that the live fetuses generated using pi6 ${ }^{\text {em1/em1 }}$ sperm in IVF or sperm heads in ICSI, like those produced by natural mating using pi6 ${ }^{e m 1 / e m 1}$ males, showed no obvious morphological abnormalities and grew to adulthood normally when fostered by host mothers. This suggests a direct or indirect requirement for paternal pi6 piRNAs in early embryogenesis.

## Changes in Spermatocyte mRNA Abundance Accompany Loss of pi6 piRNAs

To characterize the molecular phenotypes of pi6 and pi17 mutants, we used RNA-seq to measure steady-state RNA abundance in pachytene spermatocytes, diplotene spermatocytes, secondary spermatocytes, and spermatids purified from pi6 ${ }^{\mathrm{em1/em} 1}$, pi17 ${ }^{-/-}$, and C57BL/6 adult testis (Figure 6A). pi6 and pi17 precursor transcripts are abundant in meiotic pachytene spermatocytes (tetraploid), decrease in diplotene spermatocytes, and fall to low levels in post-meiotic spermatids (haploid) (Figure S5B). Compared with C57BL/6 controls, pi6 $6^{e m 1 / e m 1}$ mutants had widespread changes in mRNA abundance in pachytene spermatocytes-481 mRNAs more than doubled, while 394 fell by more than half (FDR $\leq 0.05$; Figure 6 B and S5A, and Table S2) -but caused little alteration in mRNA abundance in diplotene spermatocytes, secondary spermatocytes, or spermatids. In contrast, pi17-/- mutants showed significant changes in mRNA abundance in diplotene ( 10 mRNAs increased, 267 decreased) and secondary spermatocytes (103 mRNA increased, 400 decreased) but not in pachytene spermatocytes or spermatids (Figure S5A). Among the mRNAs that changed in the diplotene spermatocytes of pi17-/- mutants, $56 \%$ remained different from controls in secondary spermatocytes in these mutants. These data suggest that, despite similar temporal expression, pi6 piRNAs function primarily in pachytene spermatocytes, while
pi17 piRNAs may be more important at a later stage of spermatogenesis. Furthermore, 734 ( $84 \%$ ) of mRNAs with altered abundance in pi6 $6^{\text {em1/em1 }}$ pachytene spermatocytes were unchanged in any pi17-/ sorted germ cell type we examined, suggesting that distinct sets of genes are dysregulated in pi6 ${ }^{e m 1 / e m 1}$ and pi17-/- mutants.

The abundance of piRNAs from the other four major pachytene piRNA clusters, including pi17, was unaffected by loss of pi6 piRNAs, and loss of neither pi6 nor pi17 piRNAs had any significant effect on the abundance of mRNAs encoding piRNA pathway proteins (Table S3), suggesting that the changes in mRNA abundance in pi6 ${ }^{\text {em1/em1 }}$ or pi17--/ cells reflect direct regulation of target genes by pi6 or pi17 piRNAs or the downstream regulation through the direct targets of these piRNAs.

Gene Ontology (GO) analysis of the 481 up-genes found over 354 significantly enriched GO biological processes (FDR $\leq 0.01$ and enrichment $\geq 2$ ). Curiously, 106 of these GO terms correspond to developmental processes that do not normally occur in testis, suggesting a failure to suppress inappropriate programs without pi6 piRNAs. Similarly, pi6 ${ }^{\text {em1/em1 }}$ mutants show increased mRNA abundance for 20 transcription factors that normally act in undifferentiated spermatogonia or spermatogonial stem cells or the stem cells of other tissues (Table S4).

The mRNA abundance of several miRNA pathway genes also increased in pi6 ${ }^{\text {em1/em1 }}$ pachytene spermatocytes, including Lin28a (5.6-fold), Zc3h7b (5-fold), and Ajuba (5.3-fold; Figure S5C) (Dresios et al., 2005; James et al., 2010; Pilotte et al., 2011; Piskounova et al., 2011). LIN28A inhibits let-7 biogenesis by binding to the loop of pre-let-7, blocking its processing by DICER (Piskounova et al., 2008; Hagan et al., 2009; Heo et al., 2009), and let-7 promotes Lin28a degradation by binding two conserved sites in the Lin28a 3' untranslated region (Reinhart et al., 2000; Agarwal et al., 2015) predicting that let-7 levels should fall and let-7 targets should rise in pi6 ${ }^{\text {em1/em1 }}$. Indeed, in pi6em1/em1 adult testis, the aggregate abundance of let-7a, let-7b, let-7c, let$7 e$, let-7f, let-7g, and let-7i, the seven most abundant let-7 family members ( $\geq 10 \mathrm{ppm}$ in
wild-type testis) fell to less than half of wild-type, suggesting pi6 regulation of downstream target genes via let-7. Moreover, 48 predicted let-7 targets (Agarwal et al., 2015) increased in the absence of pi6 ${ }^{e m 1 / e m 1}$, including Lin28a and the mRNAs encoding three transcription factors: Sall4 (increased 8.7-fold), Elf4 (increased 7-fold), and Pbx2 (increased 6.7-fold). SALL4 is normally expressed in undifferentiated spermatogonia where it represses genes that specify somatic gene expression programs (Gassei and Orwig, 2013; Yamaguchi et al., 2015; Chan et al., 2017). ELF4 has been implicated in regulation of quiescence in hematopoietic stem cells (Lacorazza et al., 2006). Our data suggest that piRNAs, miRNAs, and transcription factors collaborate to ensure precise regulation of gene expression in spermatogenesis.

## Genes that Function in the Cilium Assembly, Cilium Motility, and Fertilization

## Pathways Decrease in mRNA Abundance upon Loss of pi6 piRNAs

GO analysis of the 394 down-genes revealed only 36 significantly enriched GO biological processes (FDR $\leq 0.01$ and fold enrichment $\geq 2$ ), of which 34 are related to the production and function of sperm and can be organized into four sets (Table S5). One set encompasses broad spermatogenesis terms (e.g., male gamete generation, 4.6 -fold enriched, FDR $=5.8 \times 10^{-11}$; sperm capacitation, 12 -fold enriched, FDR $=7.4 \times$ $10^{-3}$ ) while three sets are highly specific and match the in vivo phenotypes of pi6 mutant males. The first specific set includes cilium assembly (6.2-fold enriched, FDR $=4.1 \times$ $10^{-9}$ ) and axonemal dynein complex assembly (18-fold enriched, FDR $=1.1 \times 10^{-5}$ ). The second set contains sperm motility (13-fold enriched, FDR $=6.0 \times 10^{-10}$ ) and cilium movement involved in cell motility ( 27 -fold enriched, FDR $=2.0 \times 10^{-3}$ ). The third set involves fertilization (6.2-fold enriched, FDR $=1.7 \times 10^{-5}$ ) and binding of sperm to zona pellucida ( 12 -fold enriched, FDR $=2.3 \times 10^{-3}$ ). None of these three sets of GO terms is enriched in the 481 genes whose mRNA levels increased in pi6 ${ }^{e m 1 / e m 1}$ pachytene spermatocytes. The three sets of specific GO terms contain 28,36 , and 22 genes
whose mRNAs decreased ( 63 total and 23 shared between sets; Figure 6C and Table S6). The last two general GO terms—microtubule-based process (GO:0007017; with 27 genes whose mRNA abundance declined) and organelle assembly (GO:0070925; with 28 genes whose mRNA abundance decreased)—likely gained their enrichment from the large number of genes they share with Cilium assembly and Sperm motility processes (23 and 25 genes for the two GO terms, respectively).

## Master Regulators of Cilium Assembly and Sperm Motility

The 63 Cilium Assembly, Sperm Motility, or Fertility genes with reduced mRNA abundance in pi6 mutants include two transcription factors, Rfx2 and Foxj1, that act as master regulators of ciliogenesis (Figure 6C). Like pi6 itself, Rfx2 transcription is activated by A-MYB, and RFX2 also binds its own promoter (Horvath et al., 2009). Of the genes with decreased mRNA abundance in pi6 ${ }^{\text {em1/em1 }}$ pachytene spermatocytes, 31 both bind RFX2 and have reduced mRNA abundance in $R f x 2^{-/}$testis, suggesting they are direct targets of RFX2 (Figure 6C and Table S7) (Kistler et al., 2015). Intriguingly, 23 of these 31 RFX2-regulated genes also bind A-MYB (Table S7). A-Myb mRNA levels are normal in pi6 ${ }^{e m 1 / e m 1}$, which may account for the relatively modest decreases in the mRNA abundance of these 23 genes. Unlike RFX2, the role of FOXJ1 in sperm flagellar assembly has not been extensively studied but its role in general ciliogenesis is well established: FoxJ1-/ mouse died at or soon after birth due to absence of cilia in multiple organs (Chen et al., 1998; Blatt et al., 1999; Brody et al., 2000; Yu et al., 2008). Six genes—Tekt4, Spa17, Drc1, Rsph1, Meig1, and Tsnaxip1—out of the 394 genes with reduced mRNA abundance in pi6 ${ }^{e m 1 / e m 1}$ pachytene spermatocytes are regulated by FOXJ1 in ciliogenesis in other tissues (Yu et al., 2008; Stauber et al., 2017). Fourteen genes whose mRNA abundances decrease in pi6 ${ }^{e m 1 / e m 1}$ are uniquely annotated with the GO term Fertilization (Figure 6C and Table S6). Several are required for sperm to bind the zona pellucida or for acrosome function, including Acrosin (halved in pi6 ${ }^{\text {em1/em1 }}$
pachytene spermatocytes), Adam3 (decreased 2.5-fold), Zpbp2 (decreased 3.3-fold), and the FOXJ1-regulated gene Spa17 (decreased 5-fold). Among the genes with decreased or increased mRNA abundance in pi6 $6^{e m 1 / e m 1}$ cells, 28 have been reported to disrupt mouse or human male fertility or to play a role in spermatogenesis, spermiogenesis, or sperm function (Table S8).

## DISCUSSION

Deletion of the mouse pachytene piRNA pi6 locus results in specific, quantifiable defects in male fertility. These include impaired sperm mobility and failure in sperm to bind and penetrate the zona pellucida. The male fertility defects accompanying loss of pi6 piRNAs are specific to this locus, as deletion of the promoter of pi17, which eliminates pi17 piRNAs, had no detectable effect on male or female fertility or viability, as reported previously (Homolka et al., 2015). The phenotypic defects of pi6 mutants reflect the molecular changes-decreased steady-state abundance of mRNAs encoding proteins that function in cilial motility and fertilization. Mutations in four of these genes also cause infertility in men. The molecular changes were detected only in pachytene spermatocytes but not in diplotene spermatocytes, secondary spermatocytes, or spermatids. By contrast, RNA-seq for 17.5 dpp or adult pi6 ${ }^{\mathrm{em} 1 / e m 1}$ testes revealed no changes in mRNA abundance compared to controls. These results underscore the power of analyzing sorted germ cells.

Pachytene piRNAs have been proposed to act collectively in meiotic spermatocytes or post-meiotic spermatids to target mRNAs for destruction (Gou et al., 2014; Goh et al., 2015), but the extent to which piRNAs from different pachytene piRNA loci regulate overlapping sets of targets is unknown. Transcriptome analysis of sorted germ cells from pi6 ${ }^{e m 1 / e m 1}$ and pi17-/- mutant mice revealed distinct changes in mRNA abundance, suggesting that, despite the coordinate temporal expression of pachytene piRNAs, individual pachytene piRNA loci regulate distinct sets of genes. Given that pi6
produces 95,677 distinct piRNA sequences, the phenotypic specificity of the pi6 mutant is extraordinary. For both miRNAs and siRNAs, the seed sequence plays a central role in determining a small RNA's regulatory target. Assuming that pachytene piRNAs find their target RNAs by a similar mechanism, the sequence diversity of the small RNAs produced by individual loci is enormous: pi6 piRNAs encompass 9,880 distinct seed (g2-g8 or 7mer-m8; Bartel, 2009) and 17,304 distinct extended seed sequences (g2g9) in adult mouse testis, while pi17 generates 134,358 distinct piRNA sequences, encompassing 11,324 distinct g2-g8 seed and 21,972 distinct g2-g9 seed sequences. Yet, the g2-g9 seed sequences of the 100 most abundant pi6 piRNAs are not found among the 100 most abundant pi17 piRNAs. Furthermore, 97 of these pi6 g2-g9 seed sequences are not found among any of the 100 most-abundant piRNAs produced by pi2, pi7, pi9, or pi17. Together with pi6, these loci produce more than half of all pachytene piRNAs. The unique seed sequences of the most abundant pi6 piRNAs are consistent with the lack of compensation of loss of pi6 piRNAs by other piRNAproducing loci.

We envision that piRNAs from distinct loci target overlapping sets of genes, ensuring robust control of mRNA abundance across spermatogenesis. Our data show that pi6 piRNAs regulate-directly or by regulating upstream factors-a specific set of mRNAs whose protein products must be eliminated for successful spermiogenesis. In this view, pi6 piRNAs target mRNAs whose expression must decline at the onset of the pachynema in order to allow new sets of mRNAs to accumulate, such as the RFX2regulated genes required for ciliogenesis. While we cannot exclude a direct role for piRNAs in activating gene expression or increasing mRNA stability, we note that the overwhelming majority of siRNAs and miRNAs in plants and animals act as repressors not activators.

The phenotypic and molecular specificity of pi6 may reflect a lower degree of redundancy with other piRNA clusters. Nonetheless other piRNA clusters may partially
rescue the pi6 phenotype, accounting for the incomplete penetrance of the pi6 sterility phenotype. Conversely, the lack of a phenotype for other pachytene piRNA clusters may simply reflect greater redundancy with their piRNA-producing peers. Loss of regulation of the targets of pi17 piRNAs may be compensated by piRNAs from other loci. Testing this hypothesis is clearly a prerequisite for explaining why loss of pi6 and not pi17 piRNAs has a measurable biological consequence.

Beyond the requirement for pi6 piRNAs to produce fully functional sperm, pi6 piRNAs appear to play an additional role in embryo development. Our data suggest that the arrested development and reduced viability of embryos derived from pi6 mutant sperm reflects a paternal defect and not the embryonic genotype. Damaged sperm DNA, abnormal sperm chromatin structure, and failure to form a male pronucleus in fertilized embryos have been reported to be linked to retarded embryo development (Sakkas et al., 1998; Borini et al., 2006). Our analysis of transposon RNA abundance in pi6 mutant germ cells argues against a role for pi6 piRNAs in transposon silencing during spermatogenesis, but we cannot currently exclude a direct or indirect role for pi6 piRNAs in silencing transposons in the early embryo (Peaston et al., 2004). Of course, DNA damage might reflect incomplete repair of the double-stranded DNA breaks required for recombination, rather than transposition or transposon-induced illegitimate recombination.

How piRNAs identify their targets remains poorly understood, in part because suitable biochemical or genetic model systems are not available. The availability of a mouse mutant missing a specific set of piRNAs whose absence causes a readily detectable phenotype should provide an additional tool for understanding the basepairing rules that govern the binding of piRNAs to their RNA targets and for unraveling the regulatory network created by pachytene piRNAs.

## SUPPLEMENTAL INFORMATION

Supplemental Information includes Extended Experimental Procedures, Figures S1-5, Tables S1-S7, and Movies S1-S10.

## AUTHOR CONTRIBUTIONS

P.H.W., K.C., Y.F., Z.W., and P.D.Z. conceived and designed the experiments. P.H.W. and K.C. performed the experiments. Y.F. analyzed the sequencing data. D.M.Ö generated A-MYB ChIP-seq datasets. P.H.W., Y.F., and P.D.Z. wrote the manuscript

## ACKNOWLEDGEMENTS

We thank P. Cohen and K. Grive at Cornell University for generously sharing protocols and advice on germ cell sorting and meiotic chromosome studies; H. Florman and P. Visconti for sharing protocols and advice on sperm studies; the UMMS Transgenic Animal Modeling Core for advice on fertility test and embryo phenotype; the UMMS FACS core for advice on and help with germ cell sorting; and members of our laboratories for critical comments on the manuscript. This work was supported in part by National Institutes of Health grants GM65236 to P.D.Z. and P01HD078253 to P.D.Z. and Z.W.

## FIGURE LEGENDS

Figure 1. pi6 ${ }^{\mathrm{em} 1 / \mathrm{em} 1}$, pi $6^{\mathrm{em} 2 / \mathrm{em} 2}$, and pi17-l- promoter deletion in mice

Scissors indicate sites targeted by sgRNAs used to guide the Cas9-catalyzed promoter deletions. RNA-seq was used to measure the steady-state abundance of piRNA primary transcripts, and sequencing of $\mathrm{NaIO}_{4}$ oxidation-resistant small RNA was used to measure the abundance of mature piRNAs in 17.5 dpp testes.

See also Figure S1 and Table S1.

Figure 2. Reduced fertility in pi6em1/em1 males by natural mating
(A) Number of litters and pups per litter produced by male mice between 2-8 months of age. (B) Frequency and periodicity of litter production. Each bar represents a litter. (C) Number of embryos produced by males mated with C57BL/6 females. (D) Testis morphology analyzed by hematoxylin and eosin staining. (E) Concentration of sperm from the caudal epididymis.

See also Figure S2.

Figure 3. Fertilization defects of pi6 ${ }^{\mathrm{em} 1 / \mathrm{em1}}$ sperm revealed by IVF and ICSI
(A) Sperm function analyzed by in vitro fertilization (IVF). (B) Sperm function analyzed by intracytoplasmic sperm injection (ICSI).

Thick lines denote the median, and whiskers report the $75^{\text {th }}$ and $25^{\text {th }}$ percentiles.

See also Figure S3

Figure 4. Impaired motility and zona pellucida-binding in pi6em1/em1 sperm
(A) Strategy for zona-free IVF. (B) Comparison of sperm function in standard and zonafree IVF. (C) Acrosome reaction triggered with the $\mathrm{Ca}^{2+}$ ionophore A23187 in vitro. The results using pi6 $6^{m 1 / e m 1}$ and pi6 $6^{e m 2 / e m 2}$ sperm are combined and indicated. (D) Representative caudal epididymal spermatozoa with distinct acrosome reaction status. Green, peanut agglutinin to detect the acrosome; blue, DAPI to detect DNA.

See also Movies S1-S10.

Figure 5. Embryos derived from pi6 $6^{e m 1 / e m 1}$ sperm fail to develop
(A) Strategy for surgical transfer of fertilized two-cell embryos to surrogate mothers. (B) Rates of IVF-derived two-cell embryos that developed to term. Each uterine cartoon represents one surrogate mother, and the colored circles represent embryos. The number of embryos transferred to each side of the oviduct is also indicated. (C) Development of IVF-derived embryos. Red, the number of embryos that developed to the stage expected for the time after fertilization. (D) Rates of ICSI-derived two-cell embryos that developed to term.

See also Figure S4

Figure 6. The abundance of mRNAs encoding proteins required for sperm motility and zona pellucida-binding is decreased in pi6 ${ }^{\text {em1/em1 }}$ germ cells
(A) Strategy for purifying specific male germ cell types. (B) Volcano plots of steadystate transcript abundance in sorted testicular germ cells. Control cells were sorted from C57BL/6 testis. Each dot represents the mean abundance of an mRNA measured using three biologically independent samples. Differentially expressed transcripts ( $\geq 2$ foldchange and $\leq 0.05$ FDR) are indicated. (C) Major GO categories containing enriched

GO terms associated with genes with decreased expression in pi6 $6^{e m 1 / e m 1}$ pachytene spermatocytes (FDR $\leq 0.01$ and fold enrichment $\geq 2$ ). Genes annotated for a single category that are discussed in the main text are listed in respective categories. (D) RFX2 and A-MYB target genes with significantly decreased mRNA abundance in pi6em1/em1 pachytene spermatocytes and established functions in sperm motility and zona pellucida-binding. ChIP-seq peaks around respective transcription start sites (TSS) are shown. . RFX-2 or A-MYB occupancy is reported as fold enrichment of ChIPseq reads relative to input.

See also Table S7 for the complete list of genes regulated by pi6, RFX2, and A-MYB.

Table 1. Sperm motility measured by computer-assisted sperm analysis (CASA)

## STAR METHODS

## Mouse mutants

Mice were maintained and sacrificed according to guidelines approved by the Institutional Animal Care and Use Committee of the University of Massachusetts Medical School (A-2222-17).

Small guide RNAs (sgRNAs) flanking piRNA promoters were designed using CRISPR design tools (crispr.mit.edu/). DNA oligos containing guide sequences were cloned into pX330 vectors (Cong et al., 2013), and their cleavage activity tested in NIH3T3 cells by co-transfecting pX330 constructs containing sgRNA sequences and puromycin-resistant plasmid (pPUR) using TransIT-X2 (Mirus Bio, Madison, WI). Puromycin ( $3 \mu \mathrm{~g} / \mu \mathrm{l}$ ) was added 24 h after transfection and DNA extracted 48 h afterwards. Promoter deletions were detected by PCR using primers flanking the predicted Cas9 cleavage sites.

For mice, sgRNAs were generated by in vitro transcription and purified by electrophoresis on $8 \%(\mathrm{w} / \mathrm{v})$ polyacrylamide gels. To generate the pi $6^{\mathrm{em} 1 / \mathrm{em1}}$ and pi17-lines used in this study, in vitro transcribed sgRNAs ( $10 \mathrm{ng} / \mu \mathrm{l}$ each) targeting pi6 and pi17 were mixed with Cas9 mRNA ( $40 \mathrm{ng} / \mu \mathrm{l}$ ) and injected together into the cytoplasm of one-cell C57BL/6 zygotes (RNA only). For some founders, the sgRNA and Cas9 mRNA mixture was combined with $\mathrm{pX330}$ plasmids expressing the same four sgRNAs and Cas9 and injected into both the cytoplasm and pronuclei of one-cell C57BL/6 zygotes (RNA + DNA). For pi6 ${ }^{\text {em2/em2 }}$, in vitro transcribed sgRNAs and Cas9 mRNA were injected into the cytoplasm of one-cell C57BL/6 embryos. Embryos were transferred to pseudopregnant females using standard methods. To screen for mutant founders, DNA was extracted from small pieces of tail clipped from three-week-old pups (Truett et al., 2000). Deletions were detected by PCR, and PCR products purified and cloned into TOPO blunt vectors. Mutant sequences were determined by Sanger sequencing.

## Mouse fertility test

Each 2-8 month-old male mouse was housed with one 2-4 month-old C57BL/6 female, who was examined for the presence of a vaginal plug the following morning. When a plug was observed, the female was housed separately. For male mice who did not produce pups after 3 months ( $\sim 3$ cycles), the original female was replaced with a new female and the fertility test continued.

## Testis histology, sperm count, and sperm morphology

Mouse testes were fixed in Bouin's solution overnight, washed with $70 \%$ ethanol, embedded in paraffin, and sectioned at $5 \mu \mathrm{~m}$ thickness. Sections were stained with hematoxylin solution, countered stained with eosin solution, and imaged using Leica DMi8 brightfield microscope equipped with an $20 \times 0.4$ N.A. objective (HC PL FL L $20 \times / 0.40$ CORR PH1, Leica Microbiosystems, Buffalo Grove, IL). To quantify sperm abundance, the cauda epididymides were collected from mice and placed in phosphatebuffered saline (PBS) containing 4\% (w/v) bovine serum albumin. A few incisions were made in the epididymides with scissors to release the sperm, followed by incubation at $37^{\circ} \mathrm{C}$ and $5 \% \mathrm{CO}_{2}$ for 20 min . A $20 \mu \mathrm{l}$ aliquot of sperm suspension was diluted in $480 \mu \mathrm{l}$ of $1 \%(\mathrm{w} / \mathrm{v})$ paraformaldehyde (PFA), and sperm cells counted at $10 \times$ by brightfield microscopy. To assess sperm morphology, caudal epididymal sperm were fixed in $1 \%$ (w/v) PFA, stained with trypan blue, and a Leica DMi8 brightfield microscope equipped with an $63 \times 1.4$ N.A. oil immersion objective (HC PL APO; Leica Microbiosystems, Buffalo Grove, IL). Sperm stained with Alexa 488-conjugated PNA (see below) were also used to assess sperm morphology.

## Meiotic chromosome spreads

Meiotic chromosome spreads were prepared as described (Holloway et al., 2014). Mouse testes were incubated in hypotonic buffer ( 30 mM Tris-Cl, pH 8.2, 50 mM
sucrose, 17 mM sodium citrate, 5 mM EDTA, 0.5 mM DTT) for 30 min on ice, then small fragments of seminiferous tubules were moved to 100 mM sucrose solution and pulled apart with forceps to release germ cells. A drop of sucrose solution containing germ cells was pipetted onto a glass slide with a thin layer of $1 \times$ PBS containing $1 \%$ PFA and $0.15 \%(\mathrm{v} / \mathrm{v})$ Triton-X100 (pH 9.2) and spread by swirling. Slides were placed in a humidifying chamber for 2.5 h , air-dried, and washed twice with $1 \times$ PBS with $0.4 \%$ Photo-Flo 200 (Kodak, Rochester, NY) and once with water with $0.4 \%$ Photo-Flo 200, and air-dried. For immunostaining of meiotic chromosomes, slides were sequentially washed with (1) $1 \times$ PBS with $0.4 \%$ Photo-Flo 200, (2) $1 \times$ PBS containing $0.1 \%(v / v)$ Triton-X, and (3) blocked with PBS containing 3\% (w/v) BSA, $0.05 \%(v / v)$ Triton X-100, and $10 \%(\mathrm{v} / \mathrm{v})$ goat serum in $1 \times \mathrm{PBS}$ at room temperature. The slides were then incubated with primary antibodies, anti-SCP1 (1:1000 dilution) and anti-SCP3 (1:1000 dilution), in a humidifying chamber overnight at room temperature. Washing and blocking steps were repeated the next day, and the slides were incubated with Alexa 488- or Alexa 594-conjugated secondary antibodies (1:10,000 dilution) for 1 h at room temperature. Slides were washed thrice with $1 \times$ PBS containing $0.4 \%(v / v)$ Photo-Flo 200, once with water containing $0.4 \%$ Photo-Flo 200 mixture, air-dried in the dark, mounted by incubation in ProLong Gold Antifade Mountant with DAPI (4',6'-diamidino-2phenylindole; Thermo Fisher Scientific, Waltham, MA) overnight in the dark, and imaged using a Leica DMi8 fluorescence microscope equipped with an $63 \times 1.4$ N.A. oil immersion objective (HC PL APO; Leica Microbiosystems, Buffalo Grove, IL).

## Cell sorting by FACS

Testicular cell sorting was performed as described (Cole et al., 2014). Testes were collected, decapsulated, and incubated in $0.4 \mathrm{mg} / \mathrm{ml}$ collagenase type IV (Worthington LS004188) in $1 \times$ Grey's Balanced Salt Solution (GBSS, Sigma, G9779) at $33^{\circ} \mathrm{C}$ rotating at 150 rpm for 15 min . Separated seminiferous tubules were washed with $1 \times$ GBSS and
incubated in $0.5 \mathrm{mg} / \mathrm{ml}$ Trypsin and $1 \mu \mathrm{~g} / \mathrm{ml}$ DNase I in $1 \times$ GBSS at $33^{\circ} \mathrm{C}$ rotated at 150 rpm for 15 min . Tubules were dissociated on ice by gentle pipetting, and then $7.5 \%$ ( $\mathrm{v} / \mathrm{v}$ ) fetal bovine serum (f.c.) was added to inactivate trypsin. The cell suspension was filtered through a pre-wetted $70 \mu \mathrm{~m}$ cell strainer, and cells pelleted at $300 \times \mathrm{g}$ for 10 min at $4^{\circ} \mathrm{C}$. Cells were resuspended in $1 \times$ GBSS containing $5 \%(v / v)$ FBS, $1 \mu \mathrm{~g} / \mathrm{ml}$ DNase I, and $5 \mu \mathrm{~g} / \mathrm{ml}$ Hoechst 33342 (Thermo Fisher Scientific, Waltham, MA) and rotated at 150 rpm at $33^{\circ} \mathrm{C}$ for 45 min . Propidium iodide ( $0.2 \mu \mathrm{~g} / \mathrm{ml}$, f.c.; Thermo Fisher Scientific, Waltham, MA) was added, and cells strained through a pre-wetted $40 \mu \mathrm{~m}$ cell strainer. Cell sorting was performed on a FACSAria II (BD Biosciences, Franklin Lakes, NJ). The purity of sorted fractions was assessed by immunostaining. Secondary spermatocyte and spermatid populations were $>90 \%$ pure, and the pachytene spermatocytes and diplotene spermatocytes were $>80 \%$ pure.

## In vitro fertilization (IVF) and embryo transfer

In vitro fertilization was performed as previously described (Nagy et al., 2003) using spermatozoa from caudal epididymis of either C57BL/6, pi6 ${ }^{+/ e m 1}$, or pi $6^{e m 1 / e m 1}$ mice. Spermatozoa were incubated in human tubal fluid (HTF; $101.6 \mathrm{mM} \mathrm{NaCl}, 4.69 \mathrm{mM} \mathrm{KCl}$, $0.37 \mathrm{mM} \mathrm{KH} 2 \mathrm{PO}_{4}, 0.2 \mathrm{mM} \mathrm{MgSO} 4 \cdot 7 \mathrm{H}_{2} \mathrm{O}, 21.4 \mathrm{mM} \mathrm{Na}$-lactate, 0.33 mM Na-pyruvate, 2.78 mM glucose, $25 \mathrm{mM} \mathrm{NaHCO} 3,2.04 \mathrm{mM} \mathrm{CaCl} 2 \cdot 2 \mathrm{H}_{2} \mathrm{O}, 0.075 \mathrm{mg} / \mathrm{ml}$ Penicillin-G, $0.05 \mathrm{mg} / \mathrm{ml}$ streptomycin sulfate, $0.02 \%(\mathrm{v} / \mathrm{v})$ phenol red, $4 \mathrm{mg} / \mathrm{ml}$ BSA) with oocytes (98-146 for control sperm and 120-293 for pi6 ${ }^{\text {em1/em1 }}$ sperm) from B6SJLF1/J mice for $3-4 \mathrm{~h}$ at $37^{\circ} \mathrm{C}$ with constant $5 \% \mathrm{O}_{2}, 90 \% \mathrm{~N}_{2}$, and $5 \% \mathrm{CO}_{2}$ concentration. Oocyte viability and the presence of pronuclei were assessed under a Nikon SMZ-2B (Nikon, Tokyo, Japan) dissecting microscope. To observe embryo development, embryos were moved into potassium-supplemented simplex optimized media (KSOM; $95 \mathrm{mM} \mathrm{NaCl}, 2.5 \mathrm{mM}$ $\mathrm{KCl}, 0.35 \mathrm{mM} \mathrm{KH} \mathrm{PO}_{4}, 0.2 \mathrm{mM} \mathrm{MgSO} \cdot 7 \mathrm{H}_{2} \mathrm{O}, 10 \mathrm{mM} \mathrm{Na}$-lactate, 0.2 mM Na -pyruvate, 0.2 mM glucose, $25 \mathrm{mM} \mathrm{NaHCO}_{3}, 1.71 \mathrm{mM} \mathrm{CaCl} 2 \cdot 2 \mathrm{H}_{2} \mathrm{O}, 1 \mathrm{mM}$ L-glutamine, 0.01 mM

EDTA, $0.075 \mathrm{mg} / \mathrm{ml}$ Penicillin-G, $0.05 \mathrm{mg} / \mathrm{ml}$ streptomycin sulfate, $0.02 \%(\mathrm{v} / \mathrm{v})$ phenol red, $1 \mathrm{mg} / \mathrm{ml}$ BSA; Millipore Sigma, Burlington, MA) after IVF and assessed every 24 h . To measure birth rates, two-cell embryos were transferred to Swiss Webster pseudopregnant females, and fetuses isolated by cesarean section 18.5 d after embryo transfer.

For zona-free IVF, the zona pellucida of oocytes was removed with acid Tyrode's solution as described (Yanagimachi et al., 1976; Johnson et al., 1991).

## Intracytoplasmic sperm injection (ICSI)

Frozen caudal epididymal spermatozoa were thawed, the sperm tails detached (Nagy et al., 2003), and individual pi6 ${ }^{+/ e m 1}$ or pi6 $6^{e m 1 / e m 1}$ sperm heads injected into B6D2F1/J oocytes in Chatot-Ziomek-Bavister media (CZB; $81.62 \mathrm{mM} \mathrm{NaCl}, 4.83 \mathrm{mM} \mathrm{KCl}, 1.18$ $\mathrm{mM} \mathrm{KH} \mathrm{PO}_{4}, 1.18 \mathrm{mM} \mathrm{MgSO} 4 \cdot 7 \mathrm{H}_{2} \mathrm{O}, 25 \mathrm{mM} \mathrm{Na} 2 \mathrm{HCO}_{3}, 1.70 \mathrm{mM} \mathrm{CaCl} 2 \cdot 2 \mathrm{H}_{2} \mathrm{O}, 0.11 \mathrm{mM}$ $\mathrm{Na}_{2}$-ETDA• $2 \mathrm{H}_{2} \mathrm{O}$, 1 mM L-glutamine, 28 mM Na-lactate, 0.27 mM Na-pyruvate, 5.55 mM glucose, Penicillin-G $0.05 \mathrm{mg} / \mathrm{ml}, 0.07 \mathrm{mg} / \mathrm{ml}$ streptomycin sulfate, $4 \mathrm{mg} / \mathrm{ml}$ BSA) (Millipore Sigma, Burlington, MA) using the PiezoXpert (Eppendorf, Hamburg, Germany; Cat\#5194000024). Surviving oocytes were counted, collected, and cultured in KSOM (Millipore Sigma, Burlington, MA) at $37^{\circ} \mathrm{C}$ and $5 \% \mathrm{CO}_{2}$ for 24 h . Two-cell embryos were surgically transferred unilaterally into the oviducts of pseudopregnant Swiss Webster females. At 16.5 days after the surgery, live fetus isolated by cesarean section.

## Sperm motility

Cauda epidydimal sperm were collected from mice and placed in $37^{\circ} \mathrm{C}$ HTF media in an incubator with $5 \% \mathrm{CO}_{2}$. A drop of sperm was removed from the suspension and pipetted into a sperm counting glass chamber, then assayed by CASA or video acquisition. CASA was conducted using an IVOS II instrument (Hamilton Thorne, Beverly, MA) with the following settings: 100 frames acquired at 60 Hz ; minimal
contrast $=50 ; 4$ pixel minimal cell size; minimal static contrast $=5 ; 0 \%$ straightness (STR) threshold; $10 \mu \mathrm{~m} / \mathrm{s}$ VAP Cutoff; prog. min VAP, $20 \mu \mathrm{~m} / \mathrm{s} ; 10 \mu \mathrm{~m} / \mathrm{s}$ VSL Cutoff; 5 pixel cell size; cell intensity $=90$; static head size $=0.30-2.69$; static head intensity $=$ $0.10-1.75$; static elongation $=10-94$; slow cells motile $=$ yes; 0.68 magnification; LED illumination intensity $=3000$; IDENT illumination intensity $=3603 ; 37^{\circ} \mathrm{C}$. Agglutination of pi6em1/em1 sperm prevented CASA measurements at later times. A Nikon Diaphot 200 microscope (Nikon, Tokyo, Japan) with darkfield optics equipped with Nikon E Plan 10×/0.25 160/- Ph1 DL objective (Nikon, Tokyo, Japan), ZWO ASI 174mm Monochrome CMOS Imaging camera (ZWO, SuZhou, China), and the SharpCap software (https://docs.sharpcap.co.uk/2.9/) using darkfield at $10 \times$ magnification were used to record sperm movement at $37^{\circ} \mathrm{C}$.

## In vitro acrosome reaction assay

Acrosome reaction was assessed as described (Talbot et al., 1976). Cauda epididymides were collected from mice, placed in HTF media pre-warmed for at least 2 h in a $37^{\circ} \mathrm{C}$ incubator at $5 \% \mathrm{CO}_{2}$. A few incisions were made in the epididymides with scissors to release the sperm, followed by incubation at $37^{\circ} \mathrm{C}$ in $5 \% \mathrm{CO}_{2}$ for 90 min . Calcium ionophore A23187 (10 $\mu \mathrm{m}$ f.c. in DMSO) was added, and incubation continued for 30 min . Sperm were fixed at room temperature for 10 min by adding two volumes of $4 \%(w / v)$ PFA, pelleting at $1,000 \times g$ for 5 min , washed with $1 \times$ PBS, resuspended in fresh $1 \times$ PBS, spotted on a glass slide, and air-dried. Methanol was pipetted onto the sperm to permeabilize the cells, followed by washing with $1 \times$ PBS. Slides were incubated overnight in $10 \mu \mathrm{~g} / \mathrm{ml}$ Alexa Fluor 488-conjugated peanut agglutinin (PNA) in $1 \times$ PBS (Mortimer D., 1987), washed with $1 \times$ PBS, air-dried, and mounted with ProLong Gold Antifade Mountant with DAPI (Thermo Fisher Scientific, Waltham, MA). Sperm were imaged using a Leica DMi8 fluorescence microscope equipped with a $63 \times 1.4 \mathrm{~N} . \mathrm{A}$.
oil immersion objective (HC PL APO; Leica Microbiosystems, Buffalo Grove, IL) and analyzed using ImageJ (version 2.0.0-rc-68/1.52e; https://fiji.sc/).

## Chromatin Immunoprecipitation (ChIP) and sequencing

Frozen testes were cross-linked with $2 \%(w / v)$ formaldehyde at room temperature for 30 min using an end-over-end tumbler. Fixed tissues were homogenized in buffer containing $1 \%(\mathrm{w} / \mathrm{v})$ sodium lauryl sulfate (SDS), 10 mM EDTA, and 50 mM Tris- $\mathrm{HCl}(\mathrm{pH}$ 8.1) by 40 strokes in a Dounce tissue grinder with Pestle B (Kimble-Chase, Rockwood, TN). Lysed samples were sonicated using the E220 Covaris ultrasonicator (Covaris, Woburn, MA) to shear the chromatin to $150-200 \mathrm{bp}$ fragments and diluted $1: 10$ with a buffer containing $0.01 \%(\mathrm{w} / \mathrm{v})$ SDS, $1.1 \%(\mathrm{v} / \mathrm{v})$ Triton $\mathrm{X}-100,1.2 \mathrm{mM}$ EDTA, 16.7 mM Tris- $\mathrm{HCl}(\mathrm{pH} 8.1), 167 \mathrm{mM} \mathrm{NaCl}$. Immunoprecipitation was performed using $5.5 \mu \mathrm{~g}$ of rabbit anti-A-MYB antibody (Sigma, St. Louis, MO), DNA was extracted with phenol:chloroform:isoamyl alcohol (25:24:1) (pH 8), and ChIP-seq libraries were prepared as previously described (Li et al., 2013). Libraries were sequenced using paired-end reading on NextSeq500 (Illumina, San Diego, CA), and reads were mapped to mouse genome assembly mm10 using Bowtie2 (v2.2.5). ChIP-seq peaks were determined using MACS2 (v2.1.1) and unique mapping reads were reported in this study as fold enrichment over input.

## RNA-seq and small RNA-seq

Small RNA-seq and RNA-seq libraries were constructed and sequenced using NextSeq 500 (Illumina, San Diego, CA) as described (Fu et al., 2018). To sequence mature piRNAs, small RNA was oxidized with $25 \mathrm{mM} \mathrm{NalO}_{4}$ in 30 mM sodium borate, 30 mM boric acid (pH 8.6; Sigma Aldrich, St. Louis, MO) at $25^{\circ} \mathrm{C}$ for 30 min . RNA was precipitated with ethanol before adapter ligation. Small RNA-seq and RNA-seq reads were mapped to mouse genome assembly mm10 using piPipes (Han et al., 2015).

Transcript abundance between pi6 ${ }^{+/ e m 1}$ and C57BL/6 testes were indistinguishable (< 2fold change and FDR > 0.05). Transcripts with low abundance (<1 fpkm) in both C57BL/6 and pi6 ${ }^{\text {em1/em1 }}$ cells were excluded.

## Transposon mapping

RNA-seq reads were intersected using BEDtools (Quinlan and Hall, 2010) with Repeat Masker annotation from UCSC (downloaded from https://genome.ucsc.edu/cgibin/hgTables). Reads mapping to multiple genomic locations were apportioned. Reads for individual repeats were aggregated to obtain reads counts for repeat families.

## Statistics

All statistics were performed using R (https://www.rstudio.com/) and graphs were generated using Igor Pro v7.08 (WaveMetrics) or ggplot2 v3.0.0 (https://ggplot2.tidyverse.org/). Unless otherwise stated, Mann-Whitney-Wilcoxon test was used to calculate $p$ values.

## ACCESSION NUMBERS

All sequencing data are available through the NCBI Sequence Read Archive using accession number PRJNA480354.

## SUPPLEMENTAL FIGURE, TABLE, AND MOVIES

## Supplemental Figure Legends

Figure S1. Confirmation of mutant founder genotypes. Related to Figure 1 and Table S1.
(A) Genotyping of mutant founders by PCR. Genomic sequences of pi6 promoter region in pi6 $6^{e m 1 / e m 1}$ (B) and pi6 ${ }^{e m 2 / e m 2}$ (C) mouse lines. (D) Genomic sequences of pi17 promoter region in pi17--- mouse lines. Dashes, genomic sequences deleted by CRISPR; dots, unaltered sequence omitted for clarity.

Figure S2. pi6em1/em1 adult male phenotype. Related to Figure 2.
(A) Number of litters produced in 6 months by 2-8 month-old males. (B) Body and testis weight of 2-4 month-old pi $6^{e m 1 / e m 1}$ and pi $6^{e m 2 / e m 2}$ males. Each dot represents an individual mouse. The thick lines denote median values, and whiskers indicate the $75^{\text {th }}$ and $25^{\text {th }}$ percentiles. (C) Representative spermatozoon. (D) Representative patterns of meiotic chromosome synapsis in ${ }^{\text {pisem } 1 / e m 1}$ pachytene spermatocytes. SYCP1, Synaptonemal complex protein 1; SYCP3, Synaptonemal complex protein 3. (E) Quantification of patterns of meiotic chromosome synapsis depicted in (D).

Figure S3. Abundance of transposons in pi6em1/em1 germ cells. Related to Figure 3.
(A) Proportions of the whole genome or piRNA sequences composed of repetitive sequences. (B) Abundance of repetitive sequences in mouse germ cells. A pseudocount of 1 was added to each value. Each dot represents the mean value of three biologically independent RNA-seq experiments.

Figure S4. Pregnancy rate of surrogate mothers in IVF and ICSI experiments. Related to Figure 5.

Percent of pregnant surrogate mothers in IVF (A) and ICSI (B).

Figure S5. Transcriptome changes in pi6 ${ }^{\text {em1/em1 }}$ cells. Related to Figure 6.
(A) Number of altered genes with mRNA abundance altered by $\geq 2$-fold with FDR $\leq 0.05$ in indicated cell types. (B) Abundance of pachytene piRNAs and their precursors in C75BL/6 purified germ cells. For piRNA precursor levels, each dot represents the mean value of triplicate datasets and each error bar indicates the standard deviation. For mature piRNAs, each dot represents the mean abundance of unique-mapping reads of two duplicate datasets. (C) mRNAs with altered abundance in pi6em1/em1 cells and encoding protein with functions in meiotic chromosome organization and miRNAmediated regulation.

## Supplemental Table Legends

Table S1. Statistics of CRISPR injection for pi6 mutant generation. Related to Figure 1 and S1.

Table S2. Differentially expressed genes in pi6 ${ }^{\text {em1/em1 }}$ germ cells. Related to Figure 6 and S5.

Mean abundance (fpkm) of significantly altered mRNAs ( $\geq 2$-fold change $\cap$ FDR 0.05 ) in C57BL/6 versus pi6 ${ }^{\text {em1/em1 }}$ cells of RNA-seq triplicate datasets. A pseudocount of 0.5 was added to each value to calculate the differences. Transcripts with < 1 rpkm in both C57BL/6 and pi6em1/em1 cells prior to adding pseudocount were excluded.

Table S3. Expression of piRNA pathway genes in pi6em1/em1 cells. Related to Figure 6 and S5

Mean expression (fpkm) of piRNA genes in C57BL/6 versus pi6 ${ }^{\text {em1/em1 }}$ cells of RNA-seq triplicate datasets. A pseudocount of 0.5 was added to each value to calculate the differences. Significant changes were $\geq 2$-fold increase or decrease and FDR $\leq 0.05$.

Table S4. Transcription factors with altered mRNA abundance in pi6em1/em1 pachytene spermatocytes. Related to Figure 6 and S5.

Table S5. Gene Ontology of genes with decreased expression in pi6em1/em1 pachytene spermatocytes. Related to Figure 6 and S5.

Table S6. Genes with reduced expression in pi6 ${ }^{\mathrm{em} 1 / \mathrm{em} 1}$ pachytene spermatocytes that are mapped to major Gene Ontology categories.

## Related to Figure 6 and S5.

Table S7. RFX2 and A-MYB target genes with decreased abundance in pi6em1/em1 pachytene spermatocytes.

Related to Figure 6 and S5.

Table S8. Published male fertility genes with altered expression in pi6 ${ }^{\mathrm{em1/em} 1}$ cells. Related to Figure 6 and S5.

## Legends to Movies

Movies S1-10. pi6 ${ }^{\text {em1/em1 }}$ sperm motility.

Movie S1. C57BL/6 sperm motility at 10 minute time point.
Movie S2. pi6 $6^{e m 1 / e m 1}$ sperm motility at 10 minute time point.
Movie S3. C57BL/6 sperm motility at 90 minute time point.
Movie S4. pi6 ${ }^{e m 1 / e m 1}$ sperm motility at 90 minute time point.

Movie S5. C57BL/6 sperm motility at 3 hour time point.
Movie S6. pi6 $6^{e m 1 / e m 1}$ sperm motility at 3 hour time point

Movie S7. C57BL/6 sperm motility at 4 hour time point.
Movie S8. pi $6^{\text {em1/em1 }}$ sperm motility at 4 hour time point.
Movie S9. C57BL/6 sperm motility at 5 hour time point.

Movie S10. pi6 $6^{\mathrm{em} 1 / \mathrm{m} 1}$ sperm motility at 5 hour time point.
