24 **Abstract**

25 **Background:** Over 3,000 species of octocorals (Cnidaria, Anthozoa) inhabit an expansive range
26 of environments, from shallow tropical seas to the deep-ocean floor. They are important
27 foundation species that create coral “forests” which provide unique niches and three-dimensional
28 living space for other organisms. The octocoral genus *Renilla* inhabits sandy, continental shelves
29 in the subtropical and tropical Atlantic and eastern Pacific Oceans. *Renilla* is especially
30 interesting because it produces secondary metabolites for defense, exhibits bioluminescence, and
31 produces a luciferase that is widely used in dual-reporter assays in molecular biology. Although
32 several cnidarian genomes are currently available, the majority are from hexacorals. Here, we
33 present a *de novo* assembly of the *R. muelleri* genome, making this the first complete draft
34 genome from an octocoral.

35 **Findings:** We generated a hybrid *de novo* assembly using the Maryland Super-Read Celera
36 Assembler v.3.2.6 (MaSuRCA). The final assembly included 4,825 scaffolds and a haploid
37 genome size of 172 Mb. A BUSCO assessment found 88% of metazoan orthologs present in the
38 genome. An Augustus *ab initio* gene prediction found 23,660 genes, of which 66% (15,635) had
39 detectable similarity to annotated genes from the starlet sea anemone, *Nematostella vectensis*, or
40 to the Uniprot database. Although the *R. muelleri* genome is smaller (172 Mb) than other
41 publicly available, hexacoral genomes (256-448 Mb), the *R. muelleri* genome is similar to the
42 hexacoral genomes in terms of the number of complete metazoan BUSCOs and predicted gene
43 models.

44 **Conclusions:** The *R. muelleri* hybrid genome provides a novel resource for researchers to
45 investigate the evolution of genes and gene families within Octocorallia and more widely across

46 Anthozoa. It will be a key resource for future comparative genomics with other corals and for
47 understanding the genomic basis of coral diversity.

48

50

51 **Data Description**

52 *Organism Description*

53 Octocorallia is a subclass of Anthozoa (Phylum: Cnidaria) that is comprised of three
54 orders: Alcyonacea, Helioporacea, and Pennatulacea [1]. The Pennatulacea, commonly known as
55 sea pens, are a monophyletic group [1, 2] and are the most morphologically distinct group of
56 octocorals [1, 3]. Sea pens differ from other octocorals by exhibiting the most integrated colonial
57 behavior, with colonies arising from an axial polyp that develops into a peduncle—used to
58 anchor the animal into soft-sediments or onto hard surfaces—and a rachis that supports
59 secondary polyps [1, 3-4]. There are 14 valid families of Pennatulacea distinguished by the
60 arrangement of the secondary polyps around the rachis [1, 4]. The monogeneric family
61 Renillidae Lamarck, 1816 consists of seven species [5], unique because of their foliate colony
62 growth form [1, 4].

63 *Renilla* is found naturally on sandy, shallow sea floors along the Atlantic and Pacific
64 coasts of North and South America [3, 4, 6]. The brilliant bioluminescence and endogenous
65 fluorescence of these animals have led to them becoming important organisms in microscopy
66 and molecular biology. Isolated originally from *R. reniformis*, the enzyme luciferase (Renilla-
67 luciferin 2-monooxygenase) is used in dual luciferase reporter assays, which are commonly used
68 to study gene regulation and expression, signaling pathways, and the structure of regulatory

69 genes [7-8]. The green fluorescent protein from *Renilla* has medical applications as well as
70 general molecular biology and imagery uses [9]. In addition, the compounds produced by *Renilla*
71 for chemical defense [10] may be important sources for discovery of marine natural products
72 [11]. Thus, a genome of the octocoral *Renilla* is highly valuable to the scientific community,
73 providing a novel resource that has a range of important uses— from molecular biology to
74 comparative genomics.

75 Due to the known difficulties of resolving lengthy repeat regions with Illumina-only data
76 [12-13], we used a hybrid assembly approach [13-14], combining long-read Pacific Biosciences
77 (PacBio) data with short-read Illumina data. Studies have shown that a hybrid approach results in
78 a more complete assembly with less genome fragmentation [15-17]. Our hybrid approach used
79 low coverage PacBio reads (15x coverage) along with high coverage Illumina HiSeq reads (105x
80 coverage) to assemble a draft genome of *R. muelleri* Schultze in Kölliker, 1872, a sea pen
81 common to shallow waters of the Gulf of Mexico [6].

82

83 **Methods and Results**

84 *Data Collection*

85 A live specimen of *R. muelleri* was obtained from Gulf Specimen Marine Lab (Panacea,
86 FL, USA), which collects specimens off the panhandle of Florida in the Gulf of Mexico. Upon
87 receiving the specimen, it was flash frozen in liquid nitrogen. Genomic DNA was then extracted
88 using a modified CTAB protocol [18]. A total of 5.6 µg of DNA was sent to Novogene
89 (Sacramento, CA, USA) for library preparation and sequencing. 350 bp insert DNA libraries that
90 were PCR free were prepared and then multiplexed with other organisms on two lanes of an
91 Illumina HiSeq 2500 (150 bp PE reads). In addition, Illumina MiSeq and PacBio sequencing

92 were performed at the Weill Cornell Medicine Epigenomics Core Facility in New York. For the
93 Illumina MiSeq run, the *Renilla* library was prepared with TruSeq LT and then multiplexed with
94 eight other corals and sequenced (300 bp PE reads, MiSeq v3 Reagent kit). For PacBio
95 sequencing, a DNA library was prepared from 5 ug of DNA using the SMRTbell template prep
96 kit v 1.0. Sequencing was carried out on 10 SMRT cells on a RSII instrument using P6-C4
97 chemistry. PacBio SMRT Analysis 2.3 subread filtering module was used to produce the subread
98 files for assembly.

99 As part of another study, we sequenced total RNA from a congeneric species, *R.*
100 *reniformis*. The specimen was collected alive on the beach in North Flagler County, Florida,
101 USA. RNA was extracted from the whole adult colony and sequenced on a NextSeq500 (150 bp
102 PE reads) instrument. Library preparation and sequencing were performed at the University of
103 Florida's Interdisciplinary Center for Biotechnology.

104

105 *DNA Read Processing*

106 A total of 246,744,426 PE reads were obtained from the HiSeq and 6,725,072 PE reads
107 were obtained from the MiSeq. In total, we generated 39,029,185,500 bases of Illumina data.
108 Adapters were trimmed from all raw Illumina reads using Trimmomatic v.0.35
109 (*ILLUMINACLIP:2:30:10 LEADING:5 TRAILING:5 SLIDINGWINDOW:4:20 MINLEN:3*;
110 Trimmomatic, RRID:SCR_011848) [19], resulting in 38.98 Gb of reads. These reads were then
111 filtered with Kraken v.1.0 (Kraken, RRID:SCR_005484) [20] using the MiniKraken 8GB
112 database [21] to screen for possible microbial, viral and archaeal contamination. A total of 960
113 Mb were removed from the read files, resulting in 36.23 Gb of 150 bp reads and 1.79 Gb of 300
114 bp reads.

115 A total of 1,227,306 PacBio subreads were obtained and screened against the NCBI
116 environmental nucleotide database (env_nt.00 to env_nt.23) [22] using BLASTn v.2.2.31 (-
117 *evaluate le-10, -out_fmt 5*, RRID:SCR_001598) [23] to identify reads with environmental
118 contaminants. The subreads that did not contain contaminants were extracted using
119 MEtaGenome ANalyzer v.6.4.16 (MEGAN, RRID:SCR_011942) [24-25], resulting in 5.22 Gb
120 in 1,195,521 reads.

121

122 *RNA-Seq Read Processing*

123 We generated 119,604,588 PE reads of RNA-Seq data. We used Trimmomatic (version
124 0.36 (-phred33, ILLUMINACLIP:/usr/local/Trimmomatic-0.32/adapters/TruSeq3-
125 PE.fa:2:30:12:1:true, MINLEN:36; Trimmomatic, RRID:SCR_011848) [19] to remove Illumina
126 adapters. Trinity v 2.4.0 (--seqType fq --max_memory 250G --CPU 6 --left trim.R1.fq --right
127 trim.R2.fq --full_cleanup; Trinity RRID_SCR:013048) [26] was used to assemble the
128 transcriptome.

129

130 *Hybrid Genome Assembly*

131 Two hybrid *de novo* assemblies were performed, one with the Maryland Super-Read
132 Celera Assembler v.3.2.6 (MaSuRCA, RRID:SCR_010691) [27] and the other with SPAdes
133 v.3.11.0 (SPAdes, RRID:SCR_000131; *k-mer lengths 21,33,55,77*) [28]. The Benchmarking
134 Universal Single-Copy Orthologs v.3.0.2 (BUSCO, RRID:SCR_015008) [29] program with
135 default settings was used to screen the *Renilla* genome assemblies for 978 orthologs from the
136 Metazoan dataset as a method to evaluate the completeness of each assembly. BUSCO used
137 BLAST v.2.2.31 [23] and HMMER v.3.1.b2 (HMMER, RRID:SCR_005305) [30] in its pipeline.

138 The stats.sh program from BBMAP v.36.14 (bbmap) [31] was used to generate general assembly
139 statistics for genomes produced by both programs (Table 1).

140 The MaSuRCA assembly resulted in a 147-fold decrease in the number of scaffolds
141 generated, and a 70-fold increase in the N50 contig size (70.522 KB) as compared to the SPades
142 assembly (1.007 KB); it also had more complete BUSCOs present (Table 1). Other statistics also
143 indicate that the MaSuRCA assembly is much less fragmented than the SPAdes assembly (Table
144 1). Therefore, we used the MaSuRCA assembly in further analyses.

145 To improve the quality of the draft MaSuRCA assembly, six iterations of Pilon v.1.21
146 (Pilon, RRID:SCR_014731) [32] were used to fix assembly errors and fill assembly gaps.
147 Bowtie2 v.2.3.2 (Bowtie2, RRID:SCR_016368) [33] was used to align Illumina HiSeq and
148 Illumina MiSeq genomic reads to the draft assembly, and the resulting alignments were input to
149 Pilon, which was run on default settings. A total of 52,668 SNPs were corrected, along with
150 14,702 small insertions and 11,841 small deletions (Supplementary Table S1).

151 To remove haploid contigs that were not merged during assembly, we ran BLASTn
152 against the contigs themselves (*-max_target_seqs 10, -evalue 1e-40*) to find contigs that were
153 highly similar. The custom script *haplotypeblastn.py* version 1.0 [34] filtered the BLASTn
154 results by flagging matches that were greater than 75% identical and longer than 500 bp in
155 length. The contigs that were identified as unmerged were subsequently removed using the
156 *select_contigs.pl* script [35]. A total of 59 scaffolds, which amounted to 67 contigs and 384 kb,
157 were removed from the assembly.

158 The bbmap program stats.sh was used to generate assembly statistics on the haplotype-
159 removed assembly [i.e., “final assembly”, (Table 1)]. BUSCO analysis using the metazoan
160 orthologs was again used to estimate the completeness of the final assembly, with the flag *-long*

161 to produce higher quality training data for the downstream annotation. 857 (87.63%) orthologs
162 were present in the final assembly (Table 1). This final *R. muelleri* assembly was masked, using
163 RepeatMasker v.open-4.0.6 (*-species eukaryota -gccalc -div 50*; RepeatMasker,
164 RRID:SCR_012954) [36], for downstream gene annotation. The final annotation consists of
165 172,512,580 bp in 4,925 scaffolds.

166

167 *Genome Annotation*

168 Stampy v.1.0.31 (Stampy, RRID:SCR_005504) [37] was used to align 18.06 Gb of RNA-
169 Seq data from *R. reniformis* to the masked genome to generate intron hints. The resulting bam
170 file was processed by filtering out raw alignments using *filterBam* [38] per the recommended
171 Augustus procedures [39]. A total of 1,837,637 intron hints were generated.

172 Augustus v.3.3 (*--UTR=off --allow_hinted_splicesites=atac --alternatives-from-*
173 *evidence=true*; Augustus, RRID:SCR_008417) [40] was used to predict a gene model for *R.*
174 *muelleri*. Augustus training was performed with the hint data from *R. reniformis*, as it has been
175 shown to improve *ab initio* predictions [40-41]. The BUSCO-generated training data was also
176 included to help predict a gene model. A modified extrinsic weight file was used in Augustus to
177 penalize predicted introns that were unsupported by hint evidence and reward predicted introns
178 that were supported by hint evidence by 1e2.

179 Augustus predicted 23,660 genes that had an average exon length of 249 bp and an
180 average intron length of 524 bp as calculated by *gfstats.py* [42] (Table 2). BUSCO with the
181 metazoan lineage (*-m prot*) orthologs was used to assess the quality of the prediction, finding
182 84.87% (830/978) orthologs (Table 2).

183

184 *Functional Annotations*

185 BLASTp v.2.2.31+ (-*evaluate 1e-10 -seg yes -soft_masking true -lcase_masking*, BLASTp,
186 RRID:SCR_001010) [23] was used to map the predicted gene models of *R. muelleri* to filtered
187 protein models of another anthozoan, the sea anemone, *Nematostella vectensis* (Joint Genome
188 Institute, JGI, v 1.0) [43]. A total of 63% (14,931) of the predicted genes (23,660) mapped to *N.*
189 *vectensis* proteins (27,273). A custom python script, *filterGenes.py* [44] was used to filter the
190 matches by selecting the highest bit score; in cases where bit scores were identical, the match
191 with the highest percent length of all matches was used as a tiebreaker. Of the 14,931 genes that
192 mapped to *N. vectensis* proteins, 12,279 genes were annotated with GO function, KOG function
193 and/or InterPro domains; 8,101 genes were assigned GO terms; 11,067 genes were assigned
194 KOG functions; and 10,126 genes were assigned InterPro domains (Supplemental File 1). The
195 8,729 genes that did not hit *N. vectensis* proteins were remapped with BLASTp using a lower e-
196 value (*1e-5*) and filtered with the aforementioned python script with the same settings; an
197 additional 2,002 of the genes mapped to *N. vectensis*. Of these, 1,512 genes were annotated with
198 GO functions, KOG functions and/or InterPro domains (Supplemental File 1). The remaining
199 6,727 genes that did not match *N. vectensis* annotations were mapped to the UniProt database
200 (UniProt, RRID:SCR_002380) [45-46] with BLASTp (-*evaluate 1e-5*), and 1,844 of these were
201 assigned a UniProt function. In total, 79.36% (18,777/23,660) of the predicted gene models were
202 mapped to either *N. vectensis* predicted proteins or the UniProt database, and 66.08%
203 (15,635/23,660) of the predicted *Renilla* genes have either functional annotations or InterPro
204 domain information associated with them.

205 We also used BLASTp (-*evaluate 1e-10 -seg yes -soft_masking true -lcase_masking*) to
206 map the predicted genes against a newer *N. vectensis* dataset that was generated using RNA-Seq

207 (hereafter called the Vienna dataset) [47-48]. A total of 63% (15,001) of the predicted genes
208 (23,660) mapped to the Vienna dataset (25,729) (Supplemental File 2). As above, the predicted
209 genes that did not map were remapped with a lower e-value ($1e-5$), resulting in 2,071 additional
210 predicted genes mapping to the *N. vectensis* Vienna dataset. In total, 72.15% (17,072) of
211 predicted genes mapped to the Vienna dataset. This dataset did not have associated functional
212 annotations. Combining all gene model annotation methods, 79.82% (18,886) of genes from the
213 Augustus gene model were mapped to the JGI *N. vectensis* annotations, the *N. vectensis* Vienna
214 dataset, or the UniProt database (Supplemental Files 1-3).

215

216 *Genome Assembly Comparisons*

217 We compared the *R. muelleri* genome assembly to previously published anthozoan (e.g.,
218 corals, anemones) genomes using a variety of assessment statistics (Supplemental Table S2).
219 BUSCO was used (*-m geno*) to assess the completeness of six hexacoral genomes and a draft *R.*
220 *reniformis* genome and compare these results to the hybrid *R. muelleri* assembly (Fig. 1). We
221 found the BUSCO-completeness of our *R. muelleri* assembly (857) to be more similar to the
222 well-curated assembly of the model organism *N. vectensis* (893) [49-50] than to the other
223 anthozoans. BUSCOs from the other five hexacoral genomes were less complete, with complete
224 BUSCOs ranging from 728 (*Acropora digitifera*) to 839 (*Discosoma* sp.) [50-57]. Only 800
225 complete BUSCOs were recovered from the other hybrid assembly, the hexacoral *Montastraea*
226 *cavernosa* [57]. The only other publicly-available octocoral genome, *R. reniformis*, had
227 considerably fewer complete BUSCOs (356, Fig.1) [58].

228 The number of predicted genes was highly similar across all anthozoan genomes
229 (Supplementary Table S2). The range of predicted genes was 21,372 to 30,360 across the six

230 hexacorals. The number of predicted genes (23,360) for *R. muelleri* was similar to the 23,668
231 genes predicted for *A. digitifera*.

232 Interestingly, the genome size of *R. muelleri* is considerably smaller (172 Mb) than other
233 hexacoral genomes (256-448 Mb). Of the hexacorals, the anemone *Exaiptasia pallida* has the
234 smallest genome size of 256 Mb, while the others have genome sizes >300 Mb. As indicated by
235 [56], *E. pallida* has smaller and less frequent introns. Similar to *E. pallida*, exon sizes were
236 larger in *R. muelleri* (249 bp) compared to the hexacorals (208 to 230 bp). These results suggest
237 that there may be comparatively fewer non-coding regions in *R. muelleri* because the number of
238 predicted gene models in *R. muelleri* is similar to hexacorals, yet the exon sizes are larger and
239 the genome size is smaller in *R. muelleri*. In addition, repetitive elements in the *R. muelleri*
240 genome may be less frequent, however, this remains to be further examined.

241 We also compared the mitochondrial genome to the previously published mitogenome of
242 *R. muelleri* [59]. We used BLASTn to search for the mitogenome among the contigs (included as
243 the last contig in the assembly) and recovered the entire 18,641 bp circularized, mitogenome.
244 Compared to the published mitogenome, there were just two, single bp differences and one bp
245 indel.

246

247 **Conclusions**

248 We present the first octocoral genome assembly and showcase the feasibility of the
249 MaSuRCA hybrid assembler for marine invertebrate genomics. The *R. muelleri* genome is one of
250 the smallest anthozoan genomes discovered to date, yet it is comparable to other coral and
251 anemone genomes in terms of predicted gene models. The identification of 88% of complete
252 metazoan BUSCOs in the *R. muelleri* genome highlights that a quality genome assembly can be

253 obtained from relatively low coverage sequencing of short and long read data. Although more
254 data are needed to further increase size and reduce number of scaffolds, and further functional
255 annotation is needed, the genome of the sea pansy, *R. muelleri*, provides a novel resource for the
256 scientific community to further investigations of gene family evolution, comparative genomics,
257 and the genomic basis of coral diversity.

258

259 **Availability of supporting data**

260 The final hybrid assembly and predicted proteins generated by this study are in the *GigaDB*
261 repository [60] and on the reefgenomics website [61]. Raw Illumina and PacBio reads are
262 available in NCBI's Sequence Read Archive (PRJNA491947). RNA-Seq reads have been
263 uploaded to the European Nucleotide Archive (PRJEB28688).
