15 **Abstract**

16 Making inferences about the computations performed by neuronal circuits from synapse-level
17 connectivity maps is an emerging opportunity in neuroscience. The mushroom body (MB) is
18 well positioned for developing and testing such an approach due to its conserved neuronal
19 architecture, recently completed dense connectome, and extensive prior experimental studies
20 of its roles in learning, memory and activity regulation. Here we identify new components of the
21 MB circuit in *Drosophila*, including extensive visual input and MB output neurons (MBONs) with
22 direct connections to descending neurons. We find unexpected structure in sensory inputs, in
23 the transfer of information about different sensory modalities to MBONs, and in the modulation
24 of that transfer by dopaminergic neurons (DANs). We provide insights into the circuitry used
25 to integrate MB outputs, connectivity between the MB and the central complex and inputs to
26 DANs, including feedback from MBONs. Our results provide a foundation for further theoretical
27 and experimental work.

28

29 Introduction

30 Dramatic increases in the speed and quality of imaging, segmentation and reconstruction in
31 electron microscopy now allow large-scale, dense connectomic studies of nervous systems.
32 Such studies can reveal the chemical synapses between all neurons, generating a complete
33 connectivity map. Connectomics is particularly useful in generating biological insights when
34 applied to an ensemble of neurons with interesting behavioral functions that have already been
35 extensively studied experimentally. Knowing the effects on behavior and physiology of
36 perturbing individual cell types that can also be unambiguously identified in the connectome is
37 of considerable value. Here we present a connectomic analysis of one such neuronal
38 ensemble, the mushroom body (MB) of adult *Drosophila melanogaster*.

39 Understanding how memories of past events are formed and then used to influence ongoing
40 behavior are key challenges in neuroscience. It is generally accepted that parallel changes in
41 connection strength across multiple circuits underlie the formation of a memory and that these
42 changes are integrated to produce net changes in behavior. Animals learn to predict the value
43 of sensory cues based on temporal correlations with reward or punishment (Pavlov and
44 Thompson, 1902). Such associative learning entails lasting changes in connections between
45 neurons (reviewed in Abraham et al., 2019; Martin et al., 2000). It is now clear that different
46 parts of the brain process and store different aspects of the information learned in a single
47 event (reviewed in Josselyn and Frankland, 2018). In both flies and mammals, dopaminergic
48 neurons play a key role in conveying information about whether an event has a positive or
49 negative valence and there are compelling parallels between the molecular diversity of
50 dopaminergic cell types across these evolutionarily distant animals (Watabe-Uchida and
51 Uchida, 2018). However, we have limited understanding of how information about the outside
52 world or internal brain state reaches different dopaminergic populations. Nor do we understand
53 the nature of the information that is stored in each parallel memory system or how these parallel
54 memories interact to guide coherent behavior. We believe such processes are governed by
55 general and evolutionarily conserved principles. In particular, we believe the circuit logic that
56 allows a brain to balance the competing demands of rapid learning with long-term stability of
57 memory are likely to be the same in flies and mammals. Developing a comprehensive
58 understanding of these circuits at the resolution of individual neurons and synapses will require
59 the synergistic application of a variety of experimental methods together with theory and

60 modeling. Many of the required methods are well developed in *Drosophila*, where the circuits
61 underlying learning and memory are less complex than in mammals, and where detailed
62 anatomical knowledge of the relevant circuits, which we believe will be essential, has just now
63 become available. Here we provide analysis of the complete connectome of a circuit involved
64 in parallel processing of associative memories in adult fruit flies. The core architecture of this
65 circuit is strikingly similar to that of the vertebrate cerebellum (Figure 1; Laurent, 2002; Farris,
66 2011; Litwin-Kumar et al., 2017).

67 The MB is the major site of associative learning in insects (reviewed in Heisenberg, 2003; Modi
68 et al., 2020), and species that perform more complex behavioral tasks tend to have larger MBs
69 (O'Donnell et al., 2004; Sivinski, 1989). In the MB of each brain hemisphere, sensory stimuli
70 are represented by the sparse activity of ~2000 Kenyon cells (KCs) whose dendrites form a
71 structure called the MB calyx and whose parallel axonal fibers form the lobes of the MB (Figure
72 2; Video 1).

73 The major sensory inputs to the *Drosophila* MB are olfactory, delivered by ~150 projection
74 neurons (PNs) from the antennal lobe to the dendrites of the KCs in the MB calyx (Bates et al.,
75 2020b). KCs each receive input from an average of six PNs. For a KC to fire a spike, multiple
76 of its PN inputs need to be simultaneously activated (Gruntman and Turner, 2013). This
77 requirement, together with global feedback inhibition (Lin et al., 2014a; Papadopoulou et al.,
78 2011), ensures a sparse representation where only a small percentage of KCs are activated
79 by an odor (Honegger et al., 2011; Perez-Orive et al., 2002). The MB has a three layered
80 divergent-convergent architecture (Huerta et al., 2004; Jortner et al., 2007; Laurent, 2002;
81 Litwin-Kumar et al., 2017; Shomrat et al., 2011; Stevens, 2015) in which the coherent
82 information represented by olfactory PNs is expanded and decorrelated when delivered to the
83 KCs (Caron et al., 2013; Zheng et al., 2020). But the degree to which the structure of the
84 sensory input representation is maintained by the KCs has been debated.

85 While best studied for its role in olfactory associative learning, the MB also receives inputs from
86 several other sensory modalities. A subset of projection neurons from the antennal lobe
87 delivers information about temperature and humidity in both the larva (Eichler et al., 2017) and
88 the adult (Marin et al., 2020). Taste conditioning also requires the MB and is believed to depend
89 on specific KC populations, although the relevant inputs to these KCs have not yet been

90 reported (Kirkhart and Scott, 2015; Masek and Scott, 2010). We identified one likely path for
91 gustatory input to the MB.

92 *Drosophila* MBs are also known to be able to form memories based on visual cues (Aso et al.,
93 2014b; Brembs, 2009; Vogt et al., 2016, 2014; Liu et al., 1999; Zhang et al., 2007). Until a few
94 years ago, it was thought that visual input reached the *Drosophila* MBs using only indirect,
95 multisynaptic pathways (Farris and Van Dyke, 2015; Tanaka et al., 2008) as direct visual input
96 from the optic lobes to the MBs, well known in Hymenoptera (Ehmer and Gronenberg, 2002),
97 had not been observed in any dipteran insect (Mu et al., 2012; Otsuna and Ito, 2006). In 2016,
98 Vogt et al. (2016) identified two types of visual projection neurons (VPNs) connecting the optic
99 lobes and the MB and additional connections have been observed recently by light microscopy
100 (Li et al., 2020). We found that visual input was much more extensive than previously
101 appreciated, with about eight percent of KCs receiving predominantly visual input, and present
102 here a detailed description of neuronal pathways connecting the optic lobe and the MB. Visual
103 sensory input appears to be segregated into distinct KC populations in both the larva (Eichler
104 et al., 2017) and the adult (Vogt et al., 2016; Li et al., 2020), as is the case in honeybees (Ehmer
105 and Gronenberg, 2002). We found two classes of KCs that receive predominantly visual
106 sensory input, as well as MBONs that get the majority of their input from these segregated KC
107 populations.

108 MBONs provide the convergence element of the MB's three layer divergent-convergent circuit
109 architecture. Previous work has identified 22 types of MBONs whose dendrites receive input
110 from specific axonal segments of the KCs. The outputs of the MBONs drive learned behaviors.
111 Approximately 20 types of dopaminergic neurons (DANs) innervate corresponding regions
112 along the KC axons and are required for associative olfactory conditioning. Specifically, the
113 presynaptic arbors of the DANs and postsynaptic dendrites of the MBONs overlap in distinct
114 zones along the KC axons, defining the 15 compartmental units of the MB lobes (Aso et al.,
115 2014a; Mao and Davis, 2009; Takemura et al., 2017; Tanaka et al., 2008); Figure 2; Video 2).
116 A large body of evidence indicates that these anatomically defined compartments of the MB
117 are the units of associative learning (Aso et al., 2012, 2010, 2019, 2014a, 2014b; Aso and
118 Rubin, 2016; Berry et al., 2018; Blum et al., 2009; Bouzaiane et al., 2015; Burke et al., 2012;
119 Claridge-Chang et al., 2009; Isabel et al., 2004; Jacob and Waddell, 2020; Krashes et al., 2009;
120 S. Lin et al., 2014; Liu et al., 2012; Oswald et al., 2015; Pai et al., 2013; Plaçais et al., 2013;

121 Schwaerzel et al., 2003; Séjourné et al., 2011; Trannoy et al., 2011; Yamagata et al., 2015;
122 Zars et al., 2000).

123 The DANs innervating different MBON compartments appear to play distinct roles in signalling
124 reward versus punishment, novelty versus familiarity, the presence of olfactory cues and the
125 activity state of the fly (Aso et al., 2010; Aso and Rubin, 2016; Burke et al., 2012; Cohn et al.,
126 2015; Hattori et al., 2017; Liu et al., 2012; Sitaraman et al., 2015b; Tsao et al., 2018). These
127 differences between DAN cell types presumably reflect in large part the nature of the inputs
128 that each DAN receives, but our knowledge of these inputs is just emerging (Otto et al., 2020)
129 and is far from comprehensive. DANs adjust synaptic weights between KCs and MBONs with
130 cell type-specific rules and, in at least some cases, these differences arise from the effects of
131 co-transmitters (Aso et al., 2019). In general, a causal association of KC responses with the
132 activation of a DAN in a compartment results in depression of the synapses from the active
133 KCs onto MBONs innervating that compartment (Hige et al., 2015; Handler et al., 2019).
134 Different MB compartments are known to store and update non-redundant information as an
135 animal experiences a series of learning events (Berry et al., 2018; Felsenberg et al., 2017,
136 2018). In rodent and primate brains, recent studies have revealed that dopaminergic neurons
137 are also molecularly diverse and encode prediction errors and other information based on cell
138 type-specific rules (Hu, 2016; Menegas et al., 2018; Poulin et al., 2020; Watabe-Uchida et al.,
139 2017).

140 MBONs convey information about learned associations to the rest of the brain. Activation of
141 individual MBONs can cause behavioral attraction or repulsion, according to the compartment
142 in which their dendrites arborize (Aso et al., 2014b; Oswald et al., 2015; Perisse et al., 2016).
143 The combined output of multiple MBONs is likely to be integrated in downstream networks, but
144 we do not understand how memories stored in multiple MB compartments alter these integrated
145 signals to guide coherent and appropriate behaviors. Prior anatomical studies implied the
146 existence of multiple layers of interneurons between MBONs and descending motor pathways
147 (Aso et al., 2014a). What is the nature of information processing in those layers? Anatomical
148 studies using light microscopy provided the first hints. MBONs from different compartments
149 send their outputs to the same brain regions, suggesting that they might converge on shared
150 downstream targets. DANs often project to these same brain areas, raising the possibility of
151 direct interaction between MBONs and DANs. The functional significance of such interactions

152 has just begun to be investigated (Felsenberg et al., 2017, 2018; Ichinose et al., 2015; Jacob
153 and Waddell, 2020; Perisse et al., 2016; Zhao et al., 2018b), and studies of the *Drosophila*
154 larva, where a connectome of a numerically less complex MB is available (Eichler et al., 2017),
155 are providing valuable insights (Eschbach et al., 2020a, 2020b; Saumweber et al., 2018).

156 The recently determined connectome of a portion of an adult female fly brain (hemibrain; see
157 Figure 2-figure supplement1) provides connectivity data for ~22,500 neurons (Scheffer et al.,
158 2020). Among them, ~2,600 neurons have axons or dendrites in the MB, while ~1,500 neurons
159 are directly downstream of MBONs (using a threshold of 10 synapses from each MBON to
160 each downstream target) and ~3200 are upstream of MB dopaminergic neurons (using a
161 threshold of 5 synapses from each upstream neuron to each DAN). Thus we will consider
162 approximately one-third of the neurons in the central brain in our analysis of the MB ensemble.
163 There were some limitations resulting from not having a wiring diagram of the full central
164 nervous system, as we lacked complete connectivity information for neurons with processes
165 that extended outside the hemibrain volume (Figure 2-figure supplement 1). We were generally
166 able to mitigate these limitations by identifying the corresponding neurons in other EM or light
167 microscopic data sets when the missing information was important for our analyses. Thus the
168 hemibrain dataset was able to support a nearly comprehensive examination of the full neural
169 network underlying the MB ensemble. Studies of the larval MB are providing parallel
170 information on the structure and function of an MB with most of the same cell types, albeit fewer
171 copies of each (Eichler et al., 2017; Eschbach et al., 2020a, 2020b; Saumweber et al., 2018).
172 The microcircuits inside three MB compartments in the adult were previously described
173 (Takemura et al., 2017) and we report here that the overall organization of these three
174 compartments is conserved in a second individual of a different gender. More importantly, we
175 extend the analysis of microcircuits within the MB lobes to all 15 compartments, revealing
176 additional aspects of spatial organization within individual compartments.

177 In the current study, we were able to discover new morphological subtypes of KCs and to
178 determine the sensory inputs delivered to the dendrites of each of the ~2,000 KC. We found
179 considerable structure in the organization of those inputs and unexpectedly high levels of visual
180 input, which was the majority sensory input for two classes of KCs. This segregation of distinct
181 sensory representations into channels is maintained across the MB, such that MBONs, by
182 sampling from different KCs, have access to different sensory modalities and representations.

183 We discovered a new class of “atypical” MBONs, consisting of 14 cell types, that have part of
184 their dendritic arbors outside the MB lobes, allowing them to integrate input from KCs with other
185 information; at least five of them make strong, direct synaptic contact onto descending neurons
186 that drive motor action. We describe how MBONs from different compartments interact with
187 each other to potentially integrate and transform the signals passed from the MB to the rest of
188 the brain, revealing a number of circuit motifs including multi-layered MBON to MBON
189 feedforward networks and extensive convergence both onto common targets and onto each
190 other through axo-axonal connections. Finally, we analyzed the inputs to all 158 DANs that
191 innervate the MB. We found extensive direct feedback from MBONs to the dendrites of DANs,
192 providing a mechanism of communication within and between MB compartments. We also
193 found groups of DANs that share common inputs, providing mechanistic insights into the
194 distributed parallel processing of aversive and appetitive reinforcement and other experimental
195 observations.

196 **Results**

197 **An updated MB cell type catalog**

198 The MB can be divided into three distinct parts: the calyx, the pedunculus and the lobes (Figure
199 2; Video 1). The calyx is the input region for sensory information; KCs have their dendrites in
200 the calyx where they receive inputs from projection neurons. The calyx has subregions: the
201 main calyx (CA) and three accessory calyces. The CA gets over 90 percent of its sensory
202 information from olfactory projection neurons, whereas the smaller accessory calyces are sites
203 of non-olfactory input. The lobes are the main output region of the MB; the axons of the KCs
204 make synapses along their length, as they transverse the lobes, to the dendrites of the MBONs.
205 The pedunculus consists of parallel KC axonal fibers that connect the CA and the lobes and is
206 largely devoid of external innervation in the adult. There are five MB lobes: α , β , α' , β' and γ . In
207 *Drosophila*, the α and α' lobes are often called the vertical lobes, and the β , β' and γ lobes are
208 collectively called the medial, or horizontal, lobes. Each lobe is further divided into
209 compartments by the innervation patterns of DANs and MBONs (Figure 2; Video 2).

210 We compared the morphology of each EM reconstructed neuron to light microscopy images of
211 genetic driver lines that had been used previously to define the cell types in the MB. Guided by
212 these comparisons, we assigned cell type names that corresponded to established names to

213 the extent possible. In some cases, the availability of full EM reconstructed morphologies
214 allowed us to discern additional subtypes. We also discovered an entirely new class of MBONs,
215 the atypical MBONs, that differed from previously described MBONs in having dendrites both
216 inside and outside the MB lobes. The next few sections describe this updated catalog of MB
217 cell types, including KCs (Figures 3-5; Videos 3 and 6), other MB intrinsic and modulatory
218 neurons (Figure 3-figure supplement 1; Videos 4 and 5), DANs (Figure 6), MBONs (Figure 7)
219 and atypical MBONs (Figure 8; Figure 8-figure supplements 1-14; Videos 7-20). Most MB cell
220 types were named based on light microscopy analyses of their specific innervation areas inside
221 the MB. For instance, MBON- α 3 has its dendrites in the third compartment of the α lobe.
222 MBONs and DANs also have synonymous names based on numbering (for example, MBON14
223 for MBON- α 3), which are primarily used in this report; Figure 6-figure supplement 1 shows the
224 neurons contained in each MB compartment and lists their alternative names.

225 **KCs: the major MB intrinsic neurons and conveyors of sensory identity**

226 Associative memories in the MB are stored as altered synaptic weights between KCs, which
227 represent sensory information, and their target MBONs (Bouzaiane et al., 2015; Cassenaer
228 and Laurent, 2012; Hige et al., 2015; Oswald et al., 2015; Pai et al., 2013; Perisse et al., 2016;
229 Sejourné et al., 2011). Each of the 15 MB compartments is unique in cellular composition, and
230 individual compartments can exhibit internal substructure, which we discuss later in the paper.
231 In this next section we consider the different types of KCs that project to each compartment. In
232 later sections, we examine how the various KC types receive distinct sensory information from
233 projection neurons in the calyces and then connect differentially with MBONs to provide each
234 MBON cell type with access to a different sensory space to use in forming memories. The
235 number of KCs connected with each MBON also varies significantly from 122 (MBON10) to
236 1694 (MBON11), which can influence memory capacity and specificity.

237 We identified 1927 KCs in the right brain hemisphere. There are three major KC classes: α/β ,
238 α'/β' and γ KCs. KCs are sequentially generated from four neuroblasts in the order of γ , α'/β'
239 and α/β (Video 6; Crittenden et al., 1998; Ito et al., 1997; Lee et al., 1999; Zhu et al., 2003).
240 The axons of α/β and α'/β' KCs bifurcate at the distal pedunculus to innervate the α and β lobes
241 or the α' and β' lobes, respectively. The axons of γ KCs also branch but are confined to the γ
242 lobe. Genetic driver lines, immunohistochemistry and single cell morphology has revealed

243 further subtypes (Aso et al., 2009; Lin et al., 2007; Strausfeld et al., 2003; Tanaka et al., 2008).
244 Here we grouped 1927 KCs into 14 subtypes (Figure 3; Video 3) by applying NBLAST
245 morphological clustering (Bates et al., 2020a; Costa et al., 2016) to each major class of KCs
246 (Figure 4). Despite the dominance of olfactory input to the MB, all three major classes of KCs
247 were found to contain small subsets dedicated to non-olfactory information.

248 γ KCs: KCs that innervate the γ lobe (KC γ) have been traditionally divided into two groups,
249 dorsal (KC γ d) and main (KC γ m). Axons of γ d KCs innervate the dorsal layer of the γ lobe and
250 γ m KCs innervate the rest of the γ lobe. The dendrites of γ d KCs arborize in the ventral
251 accessory calyx (vACA), whereas those of γ m KCs are found in the CA (Aso et al., 2014a,
252 2009; Vogt et al., 2016). We identified the 701 γ KCs by excluding any KCs that innervated the
253 vertical lobes (Figure 4). We then converted their 3D morphologies (meshes) into skeletons
254 and performed an all-by-all NBLAST, which allowed us to define new KC γ subtypes and
255 enumerate the members of each type: 590 KC γ m, 99 KC γ d, eight KC γ t neurons with dendrites
256 in the anterior CA (targeted preferentially by thermo/hygrosensory neurons), and four unique
257 KC γ s neurons sampling from one or more accessory calyces (Figure 4-figure supplement 1).
258 All NBLAST clusters were validated by an independent clustering based on connectivity,
259 CBLAST (Scheffer et al., 2020), and the small number of discrepancies were resolved by
260 manual inspection (see Materials and methods).

261 α'/β' KCs: We identified 337 α'/β' KCs, which could be divided into three subtypes using all-by-
262 all NBLAST on their axons (Figure 4-figure supplement 2). The axons of each subtype formed
263 a distinct layer in both the vertical and horizontal lobes. We named these subtypes to be
264 consistent with prior nomenclature based on split-GAL4 driver lines (Figure 4-figure
265 supplement 3). There are 91 α'/β' ap1 (Figure 4-Figure supplement 2 B, B'), 127 α'/β' ap2 (Figure
266 4-figure supplement 2 D, D'), and 119 α'/β' m (Figure 4-figure supplement 2 C, C') KCs.
267 Moreover, we found that each subtype's axon layer was correlated with the position of its
268 dendrites in the CA (Figure 5E). The dendrites of the α'/β' ap1 KCs lie in the lateral accessory
269 calyx and anterior CA, areas that are preferentially targeted by thermo/hygrosensory sensory
270 projection neurons (Figure 12B).

271 α/β KCs: We identified 889 α/β KCs, which could be divided into four subtypes using all-by-all
272 NBLAST on their axons (Figure 4-figure supplement 4). The first subtype corresponds to the

273 60 KCa/ β p that form the posterior layer of the α and β lobes (Figure 4-figure supplement 4 C,
274 C'); these are the first α/β KCs to be born and have been referred to as pioneer KCa/ β s for this
275 reason (Lin et al., 2007; Zhu et al., 2003). The remaining three groups form concentric layers
276 (surface, middle, and core) in both the α and β lobes, yielding 223 KCa/ β s (Figure 4-figure
277 supplement 4 D, D'), 354 KCa/ β m (Figure 4-figure supplement 4 F, F'), and 252 KCa/ β c (Figure
278 4-figure supplement 4 E, E'). Dendrites of α/β p KCs form the dorsal accessory calyx (dACA),
279 while the rest of α/β KCs have dendrites in the CA. Our classification of α/β KC subtypes is
280 consistent with prior light level studies (Tanaka et al., 2008; Zhu et al., 2003).

281 Each of the four neuroblasts whose progeny form the MB lobes is thought to generate all
282 classes of KCs, but their exact contributions have been difficult to assess. There is no labelling
283 of neuroblast origin in EM images, but neurons derived from the same neuroblast tend to have
284 cell bodies in close proximity and primary neurites bundled into the same fiber tract. Tight
285 groupings of cell bodies are particularly evident for α/β KCs. To classify α/β KCs into four
286 neuroblast groups, we applied NBLAST to simplified skeletons of α/β KCs whose axons in the
287 lobes had been removed (Figure 5A). As expected, we found four equal-sized groups of α/β
288 KCs that we believe are each the descendants of a single neuroblast (Figure 5B). These four
289 groups form subregions in the CA and pedunculus, but their axons are scrambled in the lobes
290 (Figure 5C) as previously demonstrated by genetic methods (Lin et al., 2007; Zhu et al., 2003).

291 Upon entering the MB lobes, the axons of each KC type project to spatially segregated layers
292 in the lobes (Video 6), with the exception of γ m KCs axons which meander along the length of
293 the horizontal lobe (Figure 5-figure supplement 1B). This maintained segregation is most
294 prominent for α'/β' KCs but is also seen in α/β KCs (Figure 5E-G). The dendrites of each KC
295 type also tend to be found in the same region of the CA (Video 6; Leiss et al., 2009; Lin et al.,
296 2007; Zheng et al., 2020), which, in some cases, appears to support input specialization. These
297 features of the spatial mapping from CA to lobes and the organisation of the parallel fiber
298 system presumably evolved to facilitate associative learning. This spatial arrangement gives
299 each MBON the possibility of receiving mixed or segregated sensory information depending on
300 where that MBON extends its dendrite within the different KC layers, and, similarly, gives DANs
301 the potential ability to modify strengths of synapses from KCs conveying specific sensory
302 information. KC make synapses to neighboring KCs in the calyx, pedunculus and lobes. These

303 were described for the α lobe in Takemura et al., (2017), and Figure 5-figure supplement 2
304 provides a summary for the entire MB.

305

306 **DANs: the providers of localized neuromodulation**

307 For associative learning to occur, the neuronal pathways that convey punishment or reward
308 must converge with those that convey sensory cues. In the fly brain, this anatomical
309 convergence takes place in the compartments of MB lobes: sensory cues are represented by
310 the sparse activity of KCs and reinforcement signals by the DANs that innervate the MB lobes.
311 DANs have been traditionally grouped into two clusters, PPL1 and PAM, based on the position
312 of their cell bodies (Figure 6). PPL1 DANs innervate the vertical lobes and generally convey
313 punishment, whereas PAM DANs innervate horizontal lobes and generally convey reward (Aso
314 et al., 2019, 2012, 2010; Aso and Rubin, 2016; Burke et al., 2012; Claridge-Chang et al., 2009;
315 Felsenberg et al., 2018, 2017; Huetteroth et al., 2015; Jacob and Waddell, 2020; Lin et al.,
316 2014b; Liu et al., 2012; Mao and Davis, 2009; Schwaerzel et al., 2003). There is also a DAN
317 from the PPL2ab cluster, PPL201 (Figure 3-figure supplement 1G), that innervates the CA
318 (Mao and Davis, 2009; Tanaka et al., 2008; Zheng et al., 2018) and has been reported to play
319 a role in signalling saliency (Boto et al., 2019). We defined six PPL1 DAN cell types (PPL101-
320 PPL106; see Video 2 for PPL106) and 15 PAM DAN cell types (PAM01-PAM15). These cell
321 type classifications are consistent with previous studies (Aso et al., 2014a), except for the
322 addition of one new type, PAM15 ($\gamma 5\beta'2a$). There is only a single cell per PPL1-DAN cell type
323 in a hemisphere, and axons of each cell broadly arborize in the compartment(s) they innervate.
324 In contrast, there are between 3 and 26 cells per PAM DAN cell type, and the axonal terminals
325 of an individual PAM DAN occupy only a portion of the compartment it innervates (see Video
326 32 for PAM11 and Video 33 and Figure 32 for PAM12). Thus, it is possible to further subdivide
327 the members of PAM DAN cell types in Figure 6 into smaller groups based on morphology and
328 connectivity as described in Otto et al. (2020). We present an extensive analysis of such
329 subtypes later in the paper (Figures 28-37).

330 **MBONs: the MB's conduit to the brain for learned associations**

331 The representations of sensory cues and memory traces encoded in KC axon terminals have
332 been reported to be read out by a network of 22 types of MBONs (Aso et al., 2014a; Takemura

333 et al., 2017). We found all the previously described MBON types in the hemibrain volume
334 (Figure 7), except for MBON08 which is not present in the imaged fly. MBONs can be
335 categorized into three groups by their transmitters, which also correspond to anatomical and
336 functional groups. Dendrites of glutamatergic MBONs arborize in the medial compartments of
337 the horizontal lobes, which are also innervated by reward-representing PAM-DANs. Most
338 cholinergic MBONs arborize in the vertical lobes, in compartments that are also innervated by
339 punishment-representing PPL1-DANs. GABAergic MBONs also arborize in compartments
340 innervated by punishment-representing DANs. As described above, axon fibers of distinct
341 types of olfactory and non-olfactory KCs form layers in the MB lobes. Each MBON arborizes
342 its dendrites in a subset of layers where they receive excitatory, cholinergic synapses from KCs
343 (Barnstedt et al., 2016; Takemura et al., 2017). These KC synapses are known to be
344 presynaptically modulated by dopamine (Davis, 2005; Hige et al., 2015; Kim et al., 2007).
345 Within the MB lobes, MBONs also receive input from APL (Liu and Davis, 2009) and DPM
346 (Waddell et al., 2000) as well as from DANs (Takemura et al., 2017).

347 MBONs generally project their axons outside the MB lobes, with the exception of three
348 feedforward MBONs that project to other MB compartments (Aso et al., 2014a). As discussed
349 in detail below (Figures 18-25, Videos 23-25), MBONs most heavily innervate dorsal brain
350 areas such as the CRE, SIP and SMP (Figure 18), make direct connections to the fan-shaped-
351 body of the central complex (Figures 19 and 20), tend to converge on common targets (Figure
352 21), form a multi-layer feedforward network employing axo-axonal synapses (Figure 24), and
353 provide input to the dendrites of DANs (Figure 26).

354 **Atypical MBONs: integrators of information from inside and outside the MB lobes**

355 We identified 14 additional types of MBONs that differ from MBONs previously described in the
356 adult. We refer to these cell types as ‘atypical MBONs’ in that their dendritic arbors, in addition
357 to having extensive KC input within the MB lobes, extend outside the MB lobes into adjacent
358 brain areas (Figure 8, Figure 8-figure supplements 1-14, Videos 7-20). We reclassified
359 MBON10 and MBON20 as atypical MBONs since these two cell types had significant dendritic
360 arbors outside the MB lobes (Figure 8, Figure 8-figure supplements 1 and 2, Videos 7 and 8).
361 Twelve of the 14 atypical MBON types innervate the horizontal lobes. Unlike typical MBONs,
362 six of the atypical MBONs have significant innervation in ventral neuropils, in particular the LAL.

363 For each of the atypical MBONs we provide a figure supplement (Figure 8-figure supplements
364 1-14) that provides information on its top inputs and outputs as well as a video (Videos 7-20)
365 that displays additional morphological and connectivity features.

366 As these MBONs are described here for the first time, no experimental data yet exists on their
367 function(s) or physiology. Nevertheless, their connectivity provides clues. Each atypical MBON
368 is poised to integrate information conveyed by KCs with additional inputs to the portion of its
369 dendritic arbor that lies outside the MB lobes. Figure 8-figure supplement 15 shows which brain
370 regions supply input to each of the atypical MBONs. Frequently, these inputs include the
371 outputs of other MBONs; nine of the 14 atypical MBONs have at least two other typical or
372 atypical MBONs among the top 10 inputs to their dendrites that lie outside the lobes. Some
373 atypical MBONs receive sensory information directly. MBON28 ($\alpha'3$) receives strong
374 multiglomerular PN input, with three mPNs among its top 10 inputs outside the MB. MBON24
375 ($\beta2\gamma5$)'s top two inputs outside the MB are putative suboesophageal zone output neurons
376 (SEZONs), likely to convey mechanosensory or gustatory information based on their arbors
377 traced in the FAFB volume (Otto et al., 2020; Zheng et al., 2017) that contains the full SEZ.
378 One atypical MBON, MBON30 ($\gamma1\gamma2\gamma3$), is the only MBON that receives significant input
379 directly from the central complex; the nine cells of one fan-shaped body (FB) columnar cell
380 type, FB2-5RUB, converge in a small brain area called the rubus where they make nearly 500
381 synapses onto MBON30 (Video 15).

382 Such features suggest that the atypical MBONs might be involved in information convergence.
383 Six of the atypical MBONs project to the LAL, positioning them to connect more directly with
384 the motor network than typical MBONs which send their outputs to dorsal brain areas, a feature
385 we explore in detail later in the paper.

386 **Sensory inputs to the KCs: the calyces**

387 Sensory information is conveyed to the dendrites of KCs in specialized MB structures called
388 calyces. The main calyx (CA) contains the dendrites of 90% percent of the KCs; the dendrites
389 of the remaining KCs are in one of three accessory calyces, each with a specialized function
390 and distinct KC composition. Our work confirms and extends prior descriptions of the calyces

391 (Aso et al., 2009; Bates et al., 2020b; Butcher et al., 2012; Marin et al., 2020; Tanaka et al.,
392 2008).

393 Main calyx (CA): Olfactory sensory neurons (ORNs) that express the same odorant receptor
394 project their axons to the same glomerulus in the antennal lobe. Uniglomerular PNs (uPNs)
395 arborize their dendrites in a single glomerulus and thus receive direct sensory signals from one
396 type of ORN. These olfactory uPNs are the major sensory inputs to the main calyx (Figure 9A).
397 PNs branch when they enter the CA and their axons terminate in an average of ~6 synaptic
398 boutons, although the number varies between PN cell types (Figure 9-figure supplement 1) and
399 across individuals (Gao et al., 2019). The number of boutons per KC also differs between KC
400 cell types in the CA: $KC\alpha'/\beta'$, 4.40 +/- 1.58; $KC\alpha/\beta$, 4.67 +/- 1.78; $KC\gamma$, 8.49 +/- 2.17. The
401 synaptic boutons from a single PN can be spread over a large fraction of the calyx. Thermo-
402 and hygrosensory uPNs and multiglomerular PNs (mPNs) can also terminate in the CA, mainly
403 in the anterior (Figure 9B). PNs that convey particular odor scenes (for example decaying fruit
404 or pheromones) appear to target specific areas of the CA (Figure 9C; Figure 9-figure
405 supplement 2). We identified a subset of γ m KCs that, while receiving input from olfactory PNs
406 in CA, also extended dendritic claws outside the main calyx to receive gustatory input from a
407 single PN delivering both hygrosensory and gustatory information, providing the first
408 description of a pathway for gustatory information to reach KCs (Figure 9-figure supplement
409 3).

410 Ventral accessory calyx: The dendrites of 99 γ d KCs surround the base of the CA in a loose
411 ring and form the ventral accessory calyx (vACA; Figure 10). The accessory calyces are
412 thought to be specialized for non-olfactory information, and indeed we found that visual
413 projection neurons (VPNs) from the medulla (ME) and the lobula (LO) are the predominant
414 inputs to the γ d KCs. While the LO is largely contained in the hemibrain, the ME is not. In many
415 cases, we were able to confirm predicted ME VPns by matching neuronal fragments with their
416 complete counterparts in FAFB or light-microscopy images for conclusive annotation of ME
417 VPns (Figure 10-figure supplement 1).

418 Although the γ d KCs respond to light and are required for learning the predictive value of color
419 (Vogt et al., 2016, 2014), we have little definitive insight into the type of visual information
420 conveyed by their VPN inputs. In bees, ME and LO VPns convey specific chromatic, temporal,

421 and motion features, including sensory information required for associations bees make during
422 foraging tasks (Paulk and Gronenberg, 2008). The largest group of VPNs in *Drosophila* are
423 ipsilateral, unilateral ME neurons. The ME VPNs have dendrites in the outer part of the ME
424 (up to layer M8); the LO VPNs primarily arborize in the deeper layers of the LO (Lo4-Lo6).
425 These layers patterns are consistent with a possible role in conveying information about color
426 and intensity but notably exclude optic lobe regions that are strongly associated with motion
427 vision such as the lobula plate, ME layer M10 and LO layer Lo1 (Borst, 2014). The LO VPNs
428 are also clearly distinct from the well-studied lobula columnar cells with response to visual
429 features such as visual looming or small moving objects (Wu et al., 2016). The optic lobe has
430 a retinotopic organization. Several ME and LO VPNs have arbors that are restricted to parts of
431 the ME and LO and thus are predicted to preferentially respond to stimuli in different parts of
432 the visual field. However, we did not observe evidence for a high-resolution spatial map formed
433 by KC inputs. Local visual interneurons (LVINs) that do not themselves arborize in the optic
434 lobe but are downstream of VPNs convey additional visual information (Figure 10A). The
435 connections from VPNs and LVINs onto KC_{yd} dendrites are spatially segregated (Figure 10B).
436 LVINs are discussed in more detail below.

437 Dorsal accessory calyx: The dendrites of 60 α/β p KCs define the dorsal accessory calyx
438 (dACA) and receive predominantly visual input (Figure 11A). We found that the VPNs that
439 directly connect to α/β p KCs come mostly from the ME (Figure 11A), with a much smaller
440 contribution from the LO; VPNs projecting from the LO to the dACA have also been recently
441 noted by Li et al., (2020). However, unlike in the vACA, indirect visual input conveyed by LVINs
442 outweighs direct VPN input (Figure 11A), and VPN and LVIN inputs are less segregated (Figure
443 11B). Among these LVINs, a cluster of 13 morphologically similar neurons (SLP360, SLP362
444 and SLP371) contributes over 50% of input from all LVINs. One LVIN, MB-CP2, which has
445 been suggested to integrate multi-sensory inputs (Zheng et al., 2018), is the single strongest
446 dACA input neuron (Figure 11-figure supplement 2E) and also seems to relay input from the
447 subesophageal zone (SEZ).

448 As described above, local visual interneurons (LVINs) make up a substantial portion of the
449 inputs to γ d KCs (Figure 10-figure supplement 2) and α/β p KCs (Figure 11-figure supplement
450 1) in the vACA and dACA, respectively. LVINs get input from multiple VPNs, as well as
451 nonvisual inputs, and then convey this integrated information to KCs. The neuronal

452 morphologies and connectivity patterns of the most strongly connected LVINs are shown in
453 Figure 10-figure supplements 3-5 for the vACA and Figure 11-figure supplements 2 and 3 for
454 the dACA. We observed that clusters of LVINs, or sometimes single LVINs, receive input from
455 distinct subpopulations of VPNs. Moreover, some of the LVINs that receive inputs from similar
456 VPN subpopulations tend also to receive similar nonvisual inputs (Figure 11-figure
457 supplements 4 and 5). These observations suggest that, rather than simply relaying visual
458 information, LVINs may perform more complex processing, including integration of visual and
459 nonvisual signals.

460 Lateral accessory calyx: The lateral accessory calyx (IACA) is a small subcompartment of the
461 CA innervated by 14 α'/β' ap1 KCs (Yagi et al., 2016) and one KCys2 (Figure 12). The IACA,
462 which has been recently described in detail in Marin et al. (2020), is thought to be a
463 thermosensory center as >90% of its input comes from two PNs: the slow-adapting, cooling
464 air-responsive PN, VP3+ vPN (Liu et al., 2015; Stocker et al., 1990), which solely targets the
465 IACA (Jenett et al., 2012), and the predicted warming air-responsive VP2 adPN (Marin et al.,
466 2020). Other inputs to the IACA are described in Figure 12 and the inputs to KCys2 are
467 separately detailed in Figure 12-figure supplement 2. Most KCs in the IACA also receive inputs
468 in the CA from olfactory and thermo/hygrosensory PNs. There are direct connections to DN1a
469 clock neurons within the IACA (Yagi et al., 2016; Marin et al., 2020), as well as from the DN1a
470 neurons and the aMe23/DN1-like neuron to the 5th s-LNv and one LNd (Figure 12-figure
471 supplement 1), which could play a role in entrainment of the circadian clock by temperature
472 (Figure 12-figure supplement 2) or the adjustment of sleep patterns to different temperatures
473 (Yadlapalli et al., 2018; Alpert et al., 2020). These connections appear to reflect a function of
474 the IACA that is distinct from its role as a site of thermosensory inputs to KCs.

475 **Randomness and structure in sensory inputs to KCs**

476 Sensory input to the MB calyces shows clear structure across modalities, with visual VPN/LVIN
477 and thermo/hygrosensory PN input targeted to specific KC types (as described above and
478 discussed more fully below). This raises the question of whether olfactory inputs, in particular
479 from uPNs, also exhibit structure in their inputs to the KCs. PN synapses onto KCs in the CA
480 have a characteristic structure in which each bouton is surrounded by a claw-like KC process
481 (Yasuyama et al., 2002; Figure 9-figure supplement 1F; Video 21), which are strikingly

482 reminiscent of the mossy fiber-granule cell synapses found in the vertebrate cerebellum
483 (Huang et al., 2013). Each KC has an average of 5.6 dendritic claws in the CA and requires
484 simultaneous inputs from a combination of PNs to spike (Gruntman and Turner, 2013). The
485 synapses between the VPNS and the KC_γd dendrites have a more typical morphology, lacking
486 the claw-like structure seen in PN-to-KC synapses in the CA (Video 22).

487 Previous work suggested that KCs sample olfactory uPNs without apparent structure in both
488 the larva (Eichler et al., 2017) and the adult (Caron et al., 2013), but a recent analysis of the
489 FAFB EM dataset identified convergence of specific PNs that was inconsistent with random
490 sampling (Zheng et al., 2020; see also Gruntman and Turner, 2013). Developmental
491 mechanisms have the potential to bias PN-KC connections. Both PN and KC cell types are
492 generated in a highly stereotyped developmental order (Lee et al., 1999; Yu et al., 2010), and
493 PNs flexibly adjust the number of their presynaptic boutons based on the availability of KC
494 dendrites (Elkahlah et al., 2020).

495 To look for potential structure in olfactory uPN inputs to KCs, we computed a binary uPN-to-
496 KC connection matrix using a cutoff of five synapses. We performed principal components
497 analysis (PCA) on this connectivity, which can provide indications of structure (Caron et al.,
498 2013; Eichler et al., 2017), and compared the results with PCA on synthetic connectivity
499 matrices constructed by assuming KCs randomly sample their inputs in proportion to the total
500 number of KC connections formed with each uPN (Figure 13A). Three principal components
501 (PCs) are clearly larger than the corresponding values in the random model. Much of this
502 deviation from the random model is due to differential sampling of olfactory glomeruli by γ , α'/β'
503 and α/β KCs. In particular, input to α'/β' and α/β KCs is more strongly skewed toward specific
504 highly-represented glomeruli, most notably DP1m and DM1, while the distribution for γ KCs is
505 more uniform (Figure 13B). This suggests that the random model should be extended to allow
506 for uPN connection probabilities that depend on both the uPN and KC types. However, some
507 deviations from the extended random model are still present in the data, as can be seen when
508 PCA is performed on lobe-specific connectivity matrices (Figure 13A). Note, for example, the
509 first PC for the α/β KCs (also see Figure 13-figure supplements 1 and 2).

510 We reasoned that this residual structure might arise from the spatial organization of inputs in
511 the CA, so we analysed the spatial arrangement of uPN-to-KC connections and its impact on

512 the KC odor representation. We determined the centroid locations of uPN axonal boutons within
513 the CA by using spatial clustering of PN-to-KC synapses. Boutons belonging to uPNs from the
514 same glomerulus were nearer, on average, than those from different glomeruli (Figure 14A).
515 From these distributions, we computed the average number of boutons within a given radius
516 of each centroid (Fig. 14B). These neighboring boutons were used to construct models with
517 PN-to-KC connectivity randomly shuffled within a specified radius r (Figure 14C). This produces
518 models in which large-scale organization (at spatial scales greater than r) is preserved, while
519 local organization (at spatial scales less than r) is random (note that the model and the data
520 are identical for $r = 0$). We computed statistics that quantified properties of the KC
521 representation for our shuffled models, as a function of r . The first is the participation ratio of
522 the PN-to-KC weight matrix, which quantifies how uniformly represented each glomerulus is
523 across the inputs to all KCs. The second statistic is the dimension of the KC representation in
524 a model in which KCs fire sparsely in response to odors that activate random patterns of PNs.
525 Previous work has shown that this quantity determines the ability of a linear readout of KC
526 activity to perform odor discrimination (Litwin-Kumar et al., 2017). Our analysis reveals that the
527 participation ratio and dimension are lower for the true data than for the shuffled models, as
528 expected from non-random structure, although the effect is modest (Figure 14D). Noticeable
529 effects are present when the length scales for random shuffling is greater than approximately
530 10 μm . The effect is strongest for α/β and α'/β' KCs, while the effect of spatial organization of
531 the γ KC inputs appears to be minimal.

532 This analysis indicates that uPN inputs depend on KC subtype and on the spatial organization
533 of connections within the main calyx due to locally restricted sampling. This spatial structure
534 has only a modest effect on the dimensionality of the KC olfactory representation for simulated
535 odors that activate random ensembles of PNs, and its effect on KC inputs does not noticeably
536 persist at the level of KC outputs to MBONs (Figure 13-figure supplement 2). Nevertheless, it
537 might be relevant for specific odor categories. More broadly, our analysis of sensory inputs to
538 KCs reveals clear specialization of function across modalities supported by segregated
539 modality-specific connectivity within the accessory calyces as well as non-olfactory input to the
540 main calyx (see Figure 15-figure supplement 1A).

541 Segregation of information flow through the MB

542 If the segregation of information seen in the KCs, especially across sensory modalities, is
543 maintained at the level of MB output, this could have important implications for the specificity
544 of learned associations. To explore this possibility, we first computed the fraction of inputs that
545 KC types receive from PNs conveying different sensory modalities (Figure 15-figure
546 supplement 2A) and then we computed the fraction of input to each MBON provided by KCs
547 specialized for different sensory modalities (Figure 15-figure supplement 2B and C). The PN-
548 to-KC input fractions (Figure 15-figure supplement 2A) quantify the specialization of KCs for
549 particular sensory modalities as described above. For example, α/β p, γ d and γ s1 KCs receive
550 more than 90% of their input from VPNs and LVINs, while γ s2,3,4 KCs receive more than 50%
551 of their input from thermo-hygrosensory PNs. From this information, we divided KCs into three
552 groups: 1664 olfactory KCs, 102 olfactory + thermo/hygrosensory KCs, and 161 olfactory +
553 visual KCs. We then computed the fraction of KC input to each of the MBONs that came from
554 each of these three KC groups (Figure 15-figure supplement 2B and C; this connectivity is also
555 shown more finely divided into KC types in Figure 15-figure supplement 3). Typical MBONs
556 innervating the α'/β' lobes show a gradation of input from KCs that receive
557 thermo/hygrosensory inputs, with MBON16 ($\alpha'3$ ap) having 36% of its effective input coming
558 from this source. Typical MBONs of the α/β lobes similarly show varying degrees of KC input
559 of the olfactory + visual class. Typical MBONs of the γ lobe and CA are driven predominantly
560 by olfactory KCs. Atypical MBONs are more strongly innervated by KCs with non-olfactory
561 input.

562 By multiplying matrices of PN-KC and KC-MBON connectivity fractions, we computed an
563 effective PN-to-MBON connectivity (Figure 15, Figure 15-figure supplement 1B and C). This
564 effective connectivity shows a surprisingly high amount of non-olfactory sensory input to the
565 MBONs, with some MBONs predominantly devoted to non-olfactory modalities. While the
566 majority of the effective input to the typical MBONs is olfactory, 16% of the effective input to
567 MBONs innervating the α/β lobes, and 9% for the γ lobe MBONs, is visual, with one of the two
568 MBON19 (α 2p3p)s having 62% visual effective input (Figures 15, 15-figure supplement 1).
569 Thermo-hygrosensory PNs constitute 7% of the effective input to the α'/β' MBONs. Compared
570 to typical MBONs, atypical MBONs have a higher fraction of their input from non-olfactory
571 sources: 24% of the effective input to atypical MBONs innervating the α'/β' lobes is thermo-

572 hygro-sensory, and 26% of the effective input to γ -lobe atypical MBONs is visual. In particular,
573 MBON26 ($\beta'2d$) has 30% thermo-hygro-sensory effective input, and MBON27 ($\gamma5d$) has 80%
574 visual effective input. Thus, these MBONs may preferentially participate in non-olfactory or
575 multimodal associative memories.

576 **Downstream targets of MBONs**

577 The preceding analysis revealed segregated pathways through the MB that carry distinct
578 sensory signals. We next investigated the extent to which these pathways remained
579 segregated in the outputs of the MBONs by comparing the similarity of PN inputs between pairs
580 of MBONs with the similarity of their output targets. For this purpose, we used cosine similarity,
581 which measures the alignment between the inputs (or outputs) of the two neurons, without
582 being affected by the total number of synapses they make. It also takes into account synapse
583 counts, so that stronger connections influence the measure more than weaker connections,
584 without using any arbitrary cutoff threshold. If two neurons have no shared partners, their
585 cosine similarity will be 0, and if they target the exact same partners with the exact same relative
586 strength, their cosine similarity will be 1.

587 The similarity of the PN input to pairs of MBONs reflects the selectivities seen in Figure 15 as
588 well as revealing some more subtle structure (Figure 16, left panel). These similarities are, at
589 least to some extent, preserved at the output level (Figure 16, right panel), particularly for the
590 similarities among MBONs innervating the same lobes (Figure 16-figure supplement 1; results
591 are quantified in Figure 16-figure supplement 2). This suggests that the parallel processing of
592 different sensory modalities is, in some cases, preserved all the way from the PNs to the
593 downstream targets of the MBONs. Beyond this organization, unbiased clustering of MBONs
594 based solely on their output connectivity reveals additional groups of MBONs that have similar
595 downstream targets but different effective PN input (Figure 16-figure supplements 3 and 4).
596 For example, MBON06 ($\beta1>\alpha$), and MBON18 ($\alpha2sc$) innervate different dendritic
597 compartments (Figure 16-figure supplement 4) but have a high cosine similarity score based
598 on their output (Figure 16-figure supplement 3). Conversely, MBON20 ($\gamma1\gamma2$) and MBON25
599 ($\gamma1\gamma2$) have low cosine similarity based on their output although their dendrites innervate the
600 same compartments.

601 To look for other factors underlying the patterns of MBON output, we considered the sign of
602 MBON output as implied by neurotransmitter identity. Acetylcholine is highly predictive of
603 excitation, as is GABA for inhibition. The situation for glutamate is more ambiguous. There are
604 established cases of glutamate having inhibitory (Liu and Wilson, 2013) and excitatory
605 (Johansen et al., 1989) action. Most cells appear to express both inhibitory and excitatory
606 receptors for glutamate; for example, all six MBON and all ten DAN cell types for which data
607 exists express both inhibitory GluCl α and excitatory NMDA type receptors (Aso et al.,
608 2019). Activation of cholinergic and glutamatergic MBONs has been associated with opposing
609 behaviors, avoidance and approach, respectively (Aso et al., 2014b; Oswald et al., 2015; Perisse
610 et al., 2016), but the extent to which these result from the action of these MBONs on shared
611 targets has not been established.

612 The degree of overlap in outputs between pairs of MBONs organized by neurotransmitter type
613 (Figure 17) reveals structure that can be summarized by grouping MBONs by their transmitters
614 (Figure 17-figure supplement 1). Both cholinergic and glutamatergic MBONs show similarity
615 in their outputs with other MBONs of the same transmitter type but, interestingly, there is a
616 matching degree of similarity in the outputs across cholinergic and glutamatergic MBONs. This
617 is not seen in the similarities between MBONs using either of these transmitters and GABAergic
618 MBONs (Figure 17-figure supplement 1). Thus, assuming an inhibitory role for glutamate, the
619 convergence of cholinergic and glutamatergic MBONs on a common downstream target is
620 likely to produce a “push-pull” effect, in which competing excitatory and inhibitory influences
621 on the common target drive opposite behaviors.

622 **The distribution of the MBON outputs differs between MBONs using different** 623 **neurotransmitters**

624 The analyses above reveal MBONs with similar downstream targets but do not identify those
625 targets. We computed the propensity of MBONs, grouped by neurotransmitter type, to project
626 to different brain regions (Figure 18); our results confirm and extend observations made by light
627 microscopy (Aso et al., 2014a). All MBON types project strongly to the CRE, while cholinergic
628 and glutamatergic MBONs (but not GABAergic MBONs) project strongly to the SMP, and to a
629 lesser extent the SIP and SLP. This pattern suggests that the CRE, SMP, SIP, and SLP may
630 be sites of “push-pull” interactions as described above. GABAergic MBONs are notable in that

631 the vast majority of their projections are to the CRE, and several atypical MBONs are unique
632 in their strong projections to the LAL. Overall, these results suggest strong biases in output
633 connectivity patterns of MBON neurotransmitter types, viewed at the coarse level of brain area.
634 Finer structure is also observable in the data. For instance, the downstream projection targets
635 of MBONs exhibit spatial biases even within individual brain areas (Figure 18-figure
636 supplement 1). Importantly, although MBONs of a given neurotransmitter type often exhibit
637 related connectivity biases, they are certainly not homogeneous, consistent with unique
638 behavioral roles for individual MBONs (Figure 18-figure supplement 2).

639 **Neuronal pathways connecting the MB and the CX**

640 The MB and central complex (CX), both highly structured centers, are known to carry out
641 sophisticated computations. Communication from the MB to the CX is likely to be important for
642 conveying information about learned associations of sensory cues and external rewards or
643 punishment (Aso et al., 2014a, 2014b; Oswald et al., 2015), novelty (Hattori et al., 2017) and
644 sleep need (Sitaraman et al., 2015a; Dag et al. 2019), which, in turn, are expected to influence
645 navigation, sleep and other activities governed by the CX. We describe here the complete
646 network of strong (based on synapse number) neural pathways connecting the MB to the CX
647 (to be discussed further in a companion manuscript on the connectome of the CX).

648 We found that direct communication from the MB to the CX is limited to two pathways (Figure
649 19). The most prevalent is MBONs connecting to the dendrites of fan-shaped body (FB)
650 tangential neurons; 22 out of 34 MBON types make such direct connections and both typical
651 and atypical MBONs participate. In addition, three atypical MBONs make connections in the
652 LAL to the dendrites of three CX cell types that have axonal terminals in the nodulus (NO)
653 (Figure 19-figure supplement 1A). The FB has been divided by anatomists into multiple layers,
654 numbered ventrally to dorsally from one to nine (Figure 20; Video 26). Each tangential neuron's
655 arbors within the FB lie predominantly in a single layer and its dendrites project laterally in the
656 CRE, SMP or SIP (morphologies are shown in Video 26). We found that MBONs preferentially
657 target FB layers four (FBI4) and five (FBI5). Fifteen MBON types target FBI4 and account for
658 62% of all MBON to FB synapses; they innervate 58% of FB cell types found in this layer.
659 Thirteen MBON types target FBI5 and account for 30% of all MBON to FB synapses; they
660 innervate 43% of FB cell types found in this layer (Figure 20). Thirty-seven different FB cell

661 types get direct synaptic input from MBONs, and some cell types get input from multiple MBON
662 cell types; the fraction of each cell type's input that comes from MBONs is shown in Figure 19.
663 One cell type, CREFB4, has an unusually high level of MBON input, receiving nearly 20% of
664 its synaptic input from a combination of MBON09 ($\gamma 3\beta 1$) and MBON21 ($\gamma 4\gamma 5$) (Figure 19-figure
665 supplement 1B and C). Among the MBONs that output onto FB neurons, MBON21, MBON33
666 ($\gamma 2\gamma 3$) and MBON34 ($\gamma 2$) devote the highest fractions of their synaptic output connecting to FB
667 neurons, at 16%, 9% and 8%, respectively.

668 We also looked at MBON to CX connections that are mediated by a single interneuron. We
669 separately determined strong connections, where we required at least 50 synapses from the
670 MBON to the interneuron and then at least 50 synapses from the interneuron to the CX neuron,
671 as well as weaker connections where these thresholds were set at 20 synapses. For these
672 thresholds, we found that the only connected CX neurons were FB tangential neurons and two
673 NO neurons (eight and two at thresholds of 20 and 50, respectively). We found that all 34
674 MBON types output to FB neurons when the threshold of 20 synapses at each connecting point
675 was used (Figure 20B). Moreover, for this threshold all FB layers except layer 9 receive indirect
676 input from MBONs. Increasing the threshold to 50 synapses results in a connectivity pattern
677 that, at the level of which FB layers are connected, is very similar to that displayed by direct
678 connections (compare Figure 20 panels A and C). The direct and indirect connections appear
679 to target similar FB neurons. Over 90 percent of FB cell types that are directly postsynaptic to
680 MBONs also get indirect input through a single interneuron; conversely, 76 percent of FB cell
681 types connected by an interneuron, when using the 50-synapse threshold, also get direct
682 connections. A single interneuron can get input from multiple MBONs and then itself make
683 output onto multiple FB cell types. Figure 20-figure supplement 1 and Videos 27-29 show
684 examples of this circuit motif.

685 Connections from the CX to the MB are much more limited. In particular, we identified no cases
686 where CX neurons provide direct input to MB intrinsic cell types such as KCs, APL or DPM.
687 Indirect connections are also rare. We did identify three cases where CX neurons were
688 upstream of DANs. FB tangential neurons often have mixed arbors outside the FB and we
689 found layer 6 neurons that are presynaptic to PAM09 ($\beta 1$ ped) and PAM10 ($\beta 1$) and layer 7
690 neurons that are presynaptic to PPL105 ($\alpha' 2\alpha 2$), respectively (see Figure 34). In addition, one
691 of the 11 PAM12 ($\gamma 3$) neurons (862705904) is atypical in that it receives 12 percent of its input

692 from the FB columnar neuron FB2-5RUB (Video 33). This same FB2-5RUB cell type makes
693 strong inputs onto the atypical MBON30 ($\gamma_1\gamma_2\gamma_3$); with 451 synapses, it is MBON30's strongest
694 input outside the MB lobes (see Figure 8-figure supplement 9, Video 15 and Figure 25-figure
695 supplement 1).

696 **A network of convergence downstream of MBONs**

697 We found that different MBONs frequently share downstream targets resulting in an extensive
698 network of convergence. Such convergence would provide a mechanism to integrate the
699 outputs from different MB compartments. At a threshold of 10 synapses, ~1550 neurons are
700 downstream targets of at least one MBON, with nearly 40 percent of these (~ 600 neurons),
701 getting input from at least two MBON types (Figure 21A). Downstream targets with multiple
702 inputs are not unexpected given that the total of all MBON downstream targets is close to 10%
703 of central brain neurons and individual MBONs tend to have many downstream partners (an
704 average of 57 at the threshold we used). However, a null model in which MBON outputs are
705 randomly sampled by central brain neurons, with weighted probabilities according to their total
706 number of input synapses, yields ~3200 downstream targets, only 14% of which receive input
707 from at least two MBON types. This result indicates that MBON outputs are convergent beyond
708 what would be expected from random connectivity alone. Both typical (Figure 21B) and atypical
709 (Figure 21B') MBONs participate in such convergent networks at roughly similar levels, after
710 correcting for the smaller number of atypical MBONs, and individual cells often get input from
711 both types of MBONs. As discussed below, MBONs are highly overrepresented among the
712 downstream targets of other MBONs. Lateral horn (LH) neurons and lateral horn output
713 neurons (TON) are also frequent targets of MBON convergence, being particularly
714 overrepresented among those receiving input from seven or more MBONs. Figures 21-figure
715 supplements 1 and 2 show examples of convergence neurons with seven and 11 upstream
716 MBONs, respectively, and include MBONs with neurotransmitters of opposite sign, extreme
717 examples of the “push-pull” arrangement introduced in Figure 17.

718 **Three MBON types support a multilayer feedforward network in the MB lobes**

719 MBON05 ($\gamma_4 > \gamma_1\gamma_2$), MBON06 ($\beta_1 > \alpha$) and MBON11 ($\gamma_1\text{pedc} > \alpha/\beta$) have been previously
720 shown, based on light microscopic data, to have a high fraction of their output directed to the
721 dendrites of other MBONs within the MB lobes, providing pathways for a multi-layered

722 feedforward MBON network (Aso et al 2014a). All three of these MBONs are putatively
723 inhibitory based on their use of GABA or glutamate as neurotransmitters. We have now been
724 able to map this network comprehensively and to look at the spatial distribution of the synapses
725 from the three feedforward MBONs to their targets. It has been noted that in some cases, such
726 synapses are clustered close to the root of the target MBON's dendrites where they would be
727 well positioned to cause a shunting effect (Perisse et al., 2016; Takemura et al., 2017;
728 Felsenberg et al., 2018). We examined all feedforward connections between MBON05
729 ($\gamma_4 > \gamma_1 \gamma_2$), MBON06 ($\beta_1 > \alpha$) and MBON11 ($\gamma_1 \text{pedc} > \alpha/\beta$) and their target MBONs and found
730 that the same upstream neuron often has distinct synapse distributions on its different
731 downstream MBONs (Figure 22), as previously observed for MBON11 (Perisse et al., 2016;
732 Felsenberg et al., 2018). In several cases in the α lobe where such distributions had also been
733 mapped by Takemura et al. (2017), the two EM datasets are consistent. To quantitate these
734 distributions, we compared the distances from the root of the target MBON's dendritic tree to
735 the synapses onto it made by KCs and by feedforward MBONs. We found that, in most cases,
736 the locations of synapses from feedforward neurons closely tracked those of KCs, showing no
737 obvious spatial bias; an example is provided by the two feedforward MBONs that target
738 MBON14 (α_3): MBON06 ($\beta_1 > \alpha$) and MBON11 ($\gamma_1 \text{pedc} > \alpha/\beta$) (Figure 22B). An example of a
739 biased spatial distribution is provided by MBON06, which feeds forward onto both MBON07
740 (α_1) cells at locations that are shifted closer to the dendritic root (Figure 22D). Conversely, we
741 found MBON11 ($\gamma_1 \text{pedc} > \alpha/\beta$) synapses onto MBON03 ($\beta_2 \text{mp}$) around the edge of its dendrite
742 far away from its root (Figure 22E; consistent with Felsenberg et al., 2019), while MBON11's
743 synapses onto the two MBON07 cells are uniformly distributed (Figure 22D).

744 We also confirmed and extended the observation of Takemura et al. (2017) that MBON06 and
745 MBON11 ($\gamma_1 \text{pedc} > \alpha/\beta$) form axo-axonal connections in the α lobe in the same compartments
746 where they make feedforward connections onto the dendrites of other MBONs (Figure 22-figure
747 supplement 1); these axo-axonal connections add an additional layer of complexity to the
748 MBON feedforward network.

749 **An extensive network of MBON to MBON connections outside the MB**

750 MBONs make extensive contacts with one another outside the MB lobes, as summarized in
751 diagrammatic form in Figure 23. Contacts between a typical and an atypical MBON or between

752 two atypical MBONs can be axo-dendritic, whereas contacts between typical MBONs, with the
753 exception of the three feedforward MBONs, are almost exclusively axo-axonal. Figure 23-
754 figure supplement 1 shows all axo-axonal connections between typical MBON pairs that form
755 at least 20 synapses. Such synapses are frequently observed between glutamatergic MBONs
756 or from glutamatergic to cholinergic MBONs, as well as from GABAergic MBONs to
757 glutamatergic MBONs, but not between cholinergic MBONs and GABAergic MBONs. We then
758 examined where these synapses are located on the MBON's axons. In several cases, axo-
759 axonal synapses were highly localized and concentrated on a single axonal branch (Figure 23-
760 figure supplement 2), suggesting that they might regulate synaptic transmission to only a
761 subset of the postsynaptic MBON's downstream targets. For example, all 110 synaptic
762 connections from MBON09 ($\gamma 3\beta'1$) to MBON01 ($\gamma 5\beta'2a$) are confined to a small axonal branch
763 of MBON01. We examined the morphology of these axo-axonal synapses and found them to
764 be indistinguishable from axo-dendritic synapses made by the same MBON (Figure 23-figure
765 supplement 3).

766 **Atypical MBONs form a multilayer feedforward network**

767 Atypical MBONs receive significant input from both typical and atypical MBONs, forming a
768 multilayer feedforward network that is diagrammed in Figure 24. Connections occur both inside
769 and outside the MB lobes: panel A shows axo-dendritic connections outside the MB as well as
770 both axo-dendritic and axo-axonal connections inside the MB, while panel B shows only axo-
771 axonal connections outside the MB. This network contains three pairs of typical MBONs that
772 form reciprocal connections: MBON06 ($\beta 1 > \alpha$) with MBON11 ($\gamma 1pedc > \alpha/\beta$) through axo-axonal
773 connections within the MB (Figure 24A), and MBON09 ($\gamma 3\beta'1$) with both MBON03 ($\beta'2mp$) and
774 MBON01 ($\gamma 5\beta'2a$) through axo-axonal connections outside the MB (Figure 24B). Other than
775 the loops formed by these MBONs, the network is exclusively feedforward. MBONs 1, 5, 6, 11
776 and 30 provide a significant fraction of the connections in this network. Although the
777 neurotransmitter for MBON30 is currently unknown and the glutamatergic MBONs 1, 5 and 6
778 could have either an inhibitory or excitatory effect, it is possible that this network is dominated
779 by inhibition. It is rare for atypical MBONs to make synapses onto typical MBONs and, when
780 these occur, they are axo-axonal (Figure 24B). Only MBON29 and MBON30, non-LAL-
781 innervating atypical MBONs with axons in the dorsal brain areas, make strong axo-axonal
782 connections to typical MBONs, primarily to MBON04 ($\beta'2mp_bilateral$).

783 The network shown in Figure 24A is synaptically organized into 6 layers, with MBON26 ($\beta'2d$)
784 forming the top or 6th layer and MBON27 ($\gamma5d$), the 5th. Interestingly, of all the MBONs, these
785 two are the most highly specialized for non-olfactory input; thermo-hygrosensory input in the
786 case of MBON26 and visual for MBON27 (Figure 15; Figure 25-figure supplement 1). MBON26
787 and MBON27, as well as two of the neurons in layer 4, MBON31 ($\alpha'1$) and MBON32 ($\gamma2$), send
788 approximately 35, 60, 55 and 70 percent, respectively, of their synaptic output to the LAL, with
789 MBON27 and MBON32 innervating the contralateral LAL. The numerous pathways by which
790 information can reach these neurons, with modality-selective input that is subject to dopamine-
791 modulated learning combined with both learned information carried by other MBONs and with
792 non-MB inputs, reveals the potential for atypical MBONs to perform complex input integration.
793 We address possible functional roles for such integration in the Discussion (Figure 38).

794 **Atypical MBONs provide a direct path to motor control.**

795 To drive changes in behaviour, such as approach or avoidance, the MB must ultimately
796 communicate with motor neurons that lie in the ventral nerve cord (VNC). The brain is
797 connected to the VNC by several hundred descending neurons (DNs) that pass through the
798 neck to motor neuropils (Namiki et al., 2018). However, no direct MBON to DN connections
799 have been reported, despite many DNs having dendrites in the same dorsal brain areas that
800 serve as major MBON output sites (Figure 18; compare to Figure 4A of Namiki et al., 2018).
801 Most DNs have their dendrites in more ventral brain regions; about a dozen lie in the LAL, a
802 known CX (Hanesch et al., 1989; Heinze and Homberg, 2009; Lin et al., 2013; Namiki and
803 Kanzaki, 2016; Wolff et al., 2015) and atypical MBON output site.

804 We report here the first identified direct neuronal paths from MBONs to DNs and thus to motor
805 control. Four of the six LAL-innervating atypical MBONs are among the strongest inputs to the
806 descending neuron (DN) DNa03, which in turn provides strong input to another DN, DNa02
807 (Figure 25). DNa02 also gets weaker, but direct, input from the ipsilateral MBON32 and from
808 the MBON31s in both hemispheres. Asymmetrical activity in DNa02 has been strongly
809 implicated in the steering of a fly's walking direction (Rayshubskiy et al., 2020). The visual and
810 thermo/hygrosensory sensory input these MBONs receive is predominantly ipsilateral, allowing
811 them to convey directional sensory information that might then be used to drive approach or

812 avoidance. The other two LAL-innervating MBONs, MBON33 and MBON35, also connect to
813 neurons that we believe are DNs, but this needs to be confirmed by additional reconstruction.

814 DNa03 appears to serve as a node for convergence of directional information from the optic
815 lobes and the CX. DNa03 receives strong, direct visual input from multiple cells of a population
816 of lobula VPNs (LT51 neurons; Figure 25-figure supplement 1 and Figure 25-figure supplement
817 2A and B). Unlike the VPN neurons that innervate the accessory calyces we described earlier,
818 these LT neurons get input from layers of the lobula known to be involved in feature detection
819 (see for example, Wu et al., 2016). Moreover, DNa03 gets strong input from a population of
820 columnar FB neurons, PB1-4FB1,2,4,5LAL (PFL2; Figure 25-figure supplement 1 and Figure
821 25-figure supplement 2C and D) that are likely to convey orientation-sensitive information
822 (discussed further in a companion manuscript in preparation on the CX connectome).

823 While six atypical MBONs innervate the LAL, the other eight have their arbors in more dorsal
824 regions. We asked if any of these MBONs had identified DNs among their top 20 downstream
825 targets. In this way, we were able to establish strong connections from MBON20 to two DNs,
826 DNp42 and DNb05 (Figure 8-figure supplement 2). However, no identified DNs were found
827 among the top downstream targets of any other atypical or typical MBON.

828 We do not mean to suggest that these are the only direct MBON to DN connections. At most
829 half of the DNs expected from light level analyses (Namiki et al., 2018) have been identified in
830 the hemibrain v1.1 dataset. We also identified weaker connections from atypical MBONs to
831 other putative DNs as well as strong connections to LAL neurons that might turn out to be DNs
832 upon more extensive analysis. However, it seems likely that the connections we describe here
833 will remain among the strongest direct MBON to DN connections. Of course, all MBONs are
834 likely to eventually drive DN activity through more indirect pathways, as it is through DNs that
835 motor activity is largely controlled.

836 **Structure of DAN connectivity**

837 DANs are divided into two major groups, PPL1 and PAM, that preferentially encode punishment
838 and reward, respectively (reviewed in Modi et al., 2020). But there is growing evidence that
839 DANs provide a wider range of information to the MB about novelty, locomotion, sleep state,
840 reward or punishment omission, and safety (Aso and Rubin, 2016; Cohn et al., 2015; Dag et

841 al., 2019; Felsenberg et al., 2018, 2017; Gerber et al., 2014; Handler et al., 2019; Hattori et al.,
842 2017; Jacob and Waddell, 2020; Sitaraman et al., 2015b; Tanimoto et al., 2004).
843 Understanding how DANs represent the external world and internal brain state requires a
844 systematic investigation of their upstream inputs. Recent connectomic studies of DAN inputs
845 in the larval brain (Eschbach et al., 2020a) and to a subset of DANs in the adult (Otto et al.,
846 2020) revealed a surprising degree of heterogeneity. To understand what neuronal pathways
847 contribute to the signals that DANs convey, as well as how these signals might produce
848 learning-related changes in the strength of KC-to-MBON synapses, we characterized the inputs
849 and outputs of DANs.

850 **Feedback from MBONs to DANs**

851 We found extensive, direct synaptic connections between the axonal termini of MBONs and
852 the dendrites of DANs (Figure 26). All six PPL1 DANs and 50 of the 150 PAM DANs receive
853 direct MBON input; 20 of 22 typical MBON cell types, with representatives of all three
854 neurotransmitter types, and seven of 14 atypical MBON cell types make direct connections to
855 DANs. Connections were observed between MBONs and DANs that innervate the same
856 compartment (Figure 26A), different compartments (Figure 26B) or both the same and different
857 compartments (Figure 26C). Glutamatergic, and to a lesser extent, cholinergic, MBONs exhibit
858 a strong bias toward providing feedback to DANs of the same compartment (self-feedback). A
859 subset of PPL1 DANs was overrepresented among DANs receiving both within-compartment
860 and cross-compartment connections (Figure 26C and D).

861 Prior studies have suggested a variety of roles for feedback from MBONs to the DANs that
862 innervate the same compartment and modulate them. For example, the nutrient dependent
863 consolidation of appetitive long-term memory requires MBON07 ($\alpha 1$) activation of PAM11 ($\alpha 1$)
864 DANs (Ichinose et al., 2015) and inhibition from MBON 11 ($\gamma 1pedc > \alpha \beta$) onto the PPL101-
865 $\gamma 1pedc$ DANs (Pavlovsky et al., 2018) after training. The MBON 11 ($\gamma 1pedc > \alpha \beta$) to PPL101-
866 $\gamma 1pedc$ DAN connection has also been linked to the persistence of hunger-dependent food
867 odor seeking (Sayin et al., 2019). In addition, feedback activation of PAM01 ($\gamma 5$) by MBON01
868 ($\gamma 5\beta^2a$) is required for the maintenance of short-term courtship memory (Zhao et al., 2018b)
869 and for aversive memory extinction (Felsenberg et al., 2018; Otto et al., 2020).

870 In addition to direct connections, we also computed the effective connection strength from
871 MBONs to DANs mediated by an interneuron (Figure 26-figure supplement 1) and the
872 proportion of this feedback where an MBON feeds back onto a DAN that innervates the same
873 compartment (Figure 26-figure supplement 2). Interestingly, the same-compartment bias of
874 glutamatergic and, again to a lesser extent cholinergic, MBONs seen for direct connections is
875 also present for these indirect connections. The presence of this motif in both direct and indirect
876 MBON-DAN interactions is intriguing, and we consider its potential computational significance
877 in the Discussion.

878 **Inputs to individual DANs**

879 We characterized the inputs to the dendrites of DANs by computing cosine similarity matrices
880 of these inputs for all pairs of the 157 DANs that innervate the MB (Figure 27). An enlarged
881 view of PPL neurons is shown in Figure 27-figure supplement 1 and a simplified matrix, in
882 which the data is collapsed by compartment is shown in Figure 27-figure supplement 2.
883 Structure at the level of lobes, compartments, and even within compartments is evident. The
884 heterogeneity of input to different DANs is also clearly visible. In some cases, DANs receive
885 prominent input from particular brain areas (Figure 27-figure supplement 3, left panel). For
886 instance, α^3 and $\alpha^2\alpha^2$ DANs receive more than half their input from the SIP, γ^3 and γ^4 DANs
887 from the CRE, and $\gamma^5\beta^2a$, γ^5 , γ^1pedc , β^2a , β^2m , β^2p , and α^3 DANs from the SMP.
888 Tracing DAN inputs back to include those inputs mediated by an interneuron reveals even more
889 complex and broadly distributed inputs (Figure 27-figure supplement 3, right panel), with some
890 distinct differences from direct inputs such as vastly increased input from the CA. In general,
891 these input correlations suggest a heterogeneity in DAN function that could in principle support
892 more than a dozen different learning modalities. We identified 41 putative functional groups of
893 DANs, and an analysis of the singular values of the DAN input connectivity matrix suggests at
894 least 20 sub-compartmental zones within the MB lobes where distinct modulation by DANs
895 might occur.

896 DAN inputs need to be organized so they can convey learning-related signals to the appropriate
897 KC-MBON synapses within the MB. Such an organization should be reflected in the relationship
898 between the structure of DAN inputs and MBON outputs. For each pair of compartments, we
899 computed the similarity of the upstream inputs received by DANs innervating the two

900 compartments and the corresponding similarity of the downstream targets of MBONs from
901 those compartments (Figure 27-figure supplement 4). We identified a significant positive
902 correlation between these two similarity measures, suggesting a form of “credit assignment” in
903 which compartments whose MBONs control similar behaviors are innervated by DANs that
904 receive similar reinforcement signals. This correlation suggests that the observed
905 heterogeneity of DAN inputs is functionally relevant.

906 **PAM DANs cluster into morphological subtypes that are reflected in upstream** 907 **connectivity**

908 Grouping DANs into subtypes using hierarchical clustering based on either of two different
909 criteria, morphology or upstream connectivity, gave strikingly similar results. Figure 28 shows
910 such comparisons of morphology- and connectivity-based clusters for PAM01 (γ 5), PAM12 (γ 3)
911 and PAM11 (α 1) DANs. For α 1, morphology and input clustering generate an identical
912 dendrogram, whereas for γ 5 and γ 3 the major groupings are identical but some of the “within
913 group” orders are shifted. Finding that morphology clustering reflects input clustering
914 demonstrates that morphology is a good indicator of functionally-relevant DAN subtypes, as
915 previously demonstrated for γ 5 DANs (Otto et al., 2020).

916 Figure 28-figure supplement 1 illustrates the use of morphology to divide PAM01 (γ 5), PAM12
917 (γ 3) and PAM11 (α 1) DANs into subtypes. The most distinguishing morphological features are
918 the locations of dendritic and axonal fields, and the commissure in which a contralaterally
919 projecting axon crosses the midline. Importantly, our clustering results—using cosine input
920 similarity (Figures 27 and 29), input similarity and morphology (Figure 28)—all support the
921 division of PAM cell types into subtypes in every compartment that is innervated by a population
922 of DANs. As discussed in the next section, this sub-compartmental structure is likely to have
923 important functional consequences.

924 **PAM DAN subtypes selectively modulate subsets of KCs and specific MBONs within** 925 **single compartments**

926 We reasoned that DAN subtypes might specifically connect to particular types of KCs and
927 MBONs within a single compartment. Previous work suggested that the major axonal arbors
928 of γ 5 DAN subtypes innervate distinct subregions within the compartment (Otto et al., 2020).

929 The dense anatomical reconstruction and connectivity of neurons in the hemibrain data set
930 allowed us to examine whether such differences in morphology are reflected in connectivity
931 and, if so, whether this is a general feature of all MB compartments that are innervated by
932 multiple DANs. We first clustered DANs within a compartment based on the similarity of their
933 dendritic inputs and then, without changing the order determined by that clustering, asked if we
934 could observe structure in the pattern of their outputs onto KCs (Figure 29). In some
935 compartments, for example $\beta 1$, $\beta'1$ and $\gamma 4$, such conserved structure was indeed observed
936 indicating that DANs with similar inputs also output onto similar sets of KCs. In other
937 compartments known to have clear subtypes based on their dendritic inputs and morphology,
938 such as $\alpha 1$, $\gamma 3$ and $\gamma 5$, conserved structure was not identified by this analysis. Therefore, we
939 investigated the DANs in these three compartments in more detail, as described below, and
940 found clear examples of subtype specificity in their synapses onto KC cell types. We also found
941 selectivity in DAN subtype synapses onto MBONs within compartments innervated by multiple
942 MBON cell types, including the newly discovered atypical MBONs.

943 Each of the four defined PAM01 ($\gamma 5$) DAN subtypes is differentially connected to distinct KC
944 populations within the $\gamma 5$ compartment. This is most evident for PAM01-nc and PAM01-fb
945 DANs whose presynaptic arbors occupy distinct regions of the compartment (Figure 30A and
946 B) where they contact KC populations representing different stimulus modalities (Figure 30D
947 and E; Figure 30-figure supplements 1 and 2; Figure 15). For example, PAM01-nc DANs are
948 the major input to the visual streams of γd and $\gamma s1$ KCs (Figure 30D). In contrast, the PAM01-
949 fb DANs synapse predominantly with the main olfactory KC γ population, and weakly with the
950 γt and $\gamma s1$ KCs (Figure 30E). This arrangement suggests that DAN modulation is specific to
951 particular sensory modalities.

952 DANs are known to make synapses onto the dendrites of MBONs (Takemura et al., 2017), but
953 the physiological and behavioral roles of DAN to MBON connections are much less well
954 understood than those of DAN to KC connections; in the one case where there is functional
955 data, DAN activation induced a slow depolarization in the postsynaptic MBON (Takemura et
956 al., 2017). We found that DANs also showed selectivity within individual compartments in their
957 targeting of MBONs. For example, in $\gamma 5$ the PAM01-fb DANs synapse onto MBON01 ($\gamma 5\beta'2a$)
958 and MBON29 ($\gamma 4\gamma 5$), but not MBON27 ($\gamma 5d$), whose dendritic field preferentially occupies the
959 dorsal region of the compartment. MBON27 nevertheless receives synapses from the other

960 three classes of PAM01 DANs. Other MBONs in $\gamma 5$ also receive preferential input from specific
961 PAM01 DAN subtypes; for example, MBON24 ($\beta 2\gamma 5$) only receives synapses from the PAM01-
962 Ic DANs.

963 A similar but less complex subtype arrangement of DAN-KC and DAN-MBON connectivity is
964 evident in the $\gamma 3$ compartment, where there are two morphological DAN subtypes (Figure 28-
965 figure supplement 1E and F; Figure 39). The PAM12-md DANs provide most of the DAN input
966 to the γd KCs, whereas the γm and γt KCs are preferentially innervated by the PAM12-dd DANs
967 (Figures 30E and 32). The three MBONs with processes in the $\gamma 3$ compartment exhibit very
968 different connectivity from $\gamma 3$ DAN subtypes. PAM12-dd DANs provide all of the DAN input to
969 MBON30 ($\gamma 1\gamma 2\gamma 3$) and the majority of MBON09 ($\gamma 3\beta'1$)'s input, whereas PAM12-md DANs
970 provide the majority of MBON33 ($\gamma 2\gamma 3$)'s input.

971 The three $\alpha 1$ DAN subtypes (Figure 28-figure supplement 1 G-I) also exhibit preferential KC
972 wiring (Figure 30). For example, PAM11-nc arbors only occupy a limited portion of the $\alpha 1$
973 compartment (Figure 28-figure supplement 1I) where they preferentially innervate the visual
974 stream $\alpha/\beta p$ KCs, while avoiding $\alpha/\beta c$ and $\alpha/\beta m$ KCs. The $\alpha 1$ compartment houses the
975 dendrites of only a single MBON type, whose two members each fill the compartment (Video
976 2) and therefore receive input from all three PAM11 subtypes.

977 DAN subtype-specific wiring is also evident in the α'/β' lobes (Figure 30-figure supplement 2).
978 As an example, consider input to the thermo/hygrosensory $\alpha'/\beta'ap1$ KCs. In the $\beta'2a$
979 compartment, only PAM02-pd ($\beta'2a$) provides input to these KCs. Similarly, in $\beta'2p$, PAM05
980 DANs make abundant synapses onto the $\alpha'/\beta'ap1$ KCs, but do not contact the $\alpha'/\beta'm$ KCs.
981 Previous work has implicated $\beta'2$ DANs in thirst-dependent naive and learned water-seeking
982 (Lin et al., 2014b; Senapati et al., 2019) and the pattern of connectivity described above
983 suggests that these roles are likely to be served by specific DAN subtypes modulating specific
984 streams of KCs.

985 Our analyses suggest that selective DAN subtype innervation of modality-specific streams of
986 KCs is a general feature of all MB compartments in the horizontal lobe (Figure 30-figure
987 supplement 1). Furthermore, every MB compartment that is innervated by multiple DANs
988 contains more than one DAN subtype and generally one DAN subtype in each compartment
989 receives direct MBON input, whereas the other subtypes do not. With DAN subtypes synapsing

990 onto selective KCs and MBONs, this allows different populations of synaptic weights to be
991 independently adjusted within each compartment. This arrangement is likely to provide
992 significantly more computational bandwidth to each compartment in the MB network. We
993 further explore its function in the Discussion (Figure 38C-D).

994 **Shared input neurons suggest functional grouping of DAN subtypes across** 995 **compartments**

996 Clustering DANs based on input similarity revealed groups of DANs innervating different
997 compartments that had a significant fraction of their upstream neurons in common (Figure 27).
998 To explore the neuronal pathways that provide such shared input, we selected the 50 neurons
999 that make the largest number of synapses onto each DAN subtype. We subjected this
1000 population of 913 neurons to hierarchical clustering based on morphology, which generated
1001 235 input neuron clusters. We then analyzed how these input neuron clusters connect to the
1002 different DAN subtypes. Interestingly, several of the input clusters contained only a single
1003 neuron. Figure 31 shows 35 of these clusters, selected to illustrate the range of connectivity
1004 patterns; supplemental Table 2 shows data for all 235 clusters. In the following paragraphs we
1005 highlight some of our key findings.

1006 Studies of aversive olfactory learning have established that key teaching signals are provided
1007 by the PPL101 ($\gamma 1pedc$), PPL103 ($\gamma 2\alpha'1$) and PAM12 ($\gamma 3$) DANs. Individually blocking output
1008 from these DANs impairs aversive memory formation and their forced activation can assign
1009 aversive valence to odors (Aso et al, 2010; Aso et al., 2012; Hige et al., 2015; Perisse et al;
1010 2016; Yamagata et al., 2016; Jacob and Waddell, 2020). Our connectomics data shows that
1011 the PPL101 ($\gamma 1pedc$), PPL103 ($\gamma 2\alpha'1$) and PAM12 ($\gamma 3$) DANs share input, which supports the
1012 idea that they are driven in parallel in response to aversive/punishing cues. Several of the
1013 shared input pathways correspond to individual neurons that make synapses onto all of these
1014 aversively reinforcing DANs. These inputs provide the clearest evidence to date that this
1015 collection of aversively reinforcing DANs can be triggered together (assuming that at least
1016 some of the inputs are excitatory). Sometimes PPL101 ($\gamma 1pedc$) input neurons also connect to
1017 other DANs, which again provides insight into the functional relevance of recruiting ensembles
1018 of DANs. For example, the individual PPL101($\gamma 1pedc$) input neurons in clusters 1 and 4 and
1019 the group in cluster 13 provide weaker input to the PPL106 ($\alpha 3$) DAN. When stimulated alone

1020 during odor exposure, the PPL106 ($\alpha 3$) DAN requires more trials to code aversive learning than
1021 PPL101 ($\gamma 1pedc$), consistent with it being relatively inefficient (Aso and Rubin, 2016). However,
1022 multiple spaced aversive training trials strongly depress the conditioned odor-response of
1023 MBON14 ($\alpha 3$) (Jacob and Waddell, 2020). We also found that PPL101 ($\gamma 1pedc$) frequently
1024 shares input with PPL102 ($\gamma 1$). Although, these DANs have overlapping innervation in the $\gamma 1$
1025 compartment, to date most attention has been focused on the PPL101 ($\gamma 1pedc$) DAN. It will
1026 therefore be important to determine the role of PPL102 ($\gamma 1$).

1027 Whereas each aversively reinforcing PPL1 DAN is a single neuron, there are 10-11 PAM12
1028 DANs innervating $\gamma 3$ (one PAM12 appears to be incomplete in this data set). An unexpected
1029 finding from this study is that the PAM12 ($\gamma 3$) DAN population is comprised of at least two clear
1030 subtypes that are notable for the DANs with which they share input. Moreover, analysis of the
1031 inputs to the two PAM12 ($\gamma 3$) DAN subtypes provides evidence that they convey opposite
1032 valence. Four single neuron clusters (clusters 1, 2, 4 & 5) preferentially connect to PAM12-dd
1033 ($\gamma 3$) DANs and the negative valence PPL1 DANs, PPL101 ($\gamma 1pedc$) and PPL102 ($\gamma 1$), implying
1034 that PAM12-dd might also signal negative valence. PAM12-md ($\gamma 3$) DANs have very different
1035 connectivity defined by strong input from the four neurons in cluster 6 (Figures 31 and 32D),
1036 which also provides input to 3 of the 4 subtypes of PAM08 ($\gamma 4$) DANs and PAM07 ($\gamma 4 < \gamma 1 \gamma 2$)
1037 DANs. These shared inputs suggest that PAM12-md signals positive valence. It is noteworthy
1038 that prior studies have implicated PAM12 DANs in both aversive and appetitive memory. At
1039 least some PAM12 DANs are shock responsive (Cohn et al., 2015; Jacob and Waddell, 2020)
1040 and can provide aversive reinforcement (Aso et al., 2012), but it has also been shown that their
1041 inhibition following sugar ingestion is required and even sufficient to assign positive value to
1042 odors during learning (Yamagata et al., 2016). Furthermore, a recent study of spaced aversive
1043 conditioning showed that the $\gamma 3$ DANs are required for flies to gradually learn that the odor that
1044 is experienced without shock is safe (Jacob and Waddell, 2020). It will be important to clarify
1045 how the different $\gamma 3$ DANs contribute to these learning processes.

1046 Prior functional studies have suggested that different aversively reinforcing stimuli, such as
1047 electric shock, high and low heat, and bitter taste converge onto the PPL101 ($\gamma 1pedc$) and
1048 PPL103 ($\gamma 2\alpha'1$) DANs (Das et al., 2014; Galili et al., 2014; Tomchik, 2013). One might therefore
1049 expect to find connectivity consistent with such convergence. Interestingly, rather than finding
1050 clear streams of input to these PPL1 DANs and the PAM12 ($\gamma 3$) DANs, the identified individual

1051 input neurons emanate from discrete brain areas, consistent with these neurons conveying
1052 unique information. Only one neuron in cluster 28 projects from the SEZ and connects to
1053 PPL101 (γ 1pedc) and PPL106 (α 3). It may therefore relay the negative valence of bitter taste.
1054 Besides this SEZON we did not find other obvious inputs from primary sensory processing
1055 areas, or ascending pathways that might come from the ventral nerve cord and could for
1056 example relay shock from the legs. It therefore seems likely that most information conveyed to
1057 aversively reinforcing DANs has been pre-processed en route from the periphery.

1058 Input connectivity also revealed insights into the overall organization of the PAM DANs,
1059 uncovering a remarkable heterogeneity and revealing a highly parallel architecture of rewarding
1060 reinforcement. Prior studies have established that PAM DANs are required for flies to learn
1061 using different types of reward, and that their artificial activation (or inactivation in the case of
1062 γ 3 DANs) can assign positive valence to odors during learning (Liu et al., 2012; Burke et al.,
1063 2012; Perisse et al., 2013; Aso et al., 2014b; Huetteroth et al., 2015; Yamagata et al., 2015,
1064 2016). In addition, a number of studies have implicated unique populations of PAM DANs in
1065 reinforcing different positive experiences, for example, the sweet taste and nutrient value of
1066 sugar (Huetteroth et al., 2015; Yamagata et al., 2015), water (Lin et al., 2014, Shyu et al.,
1067 2017), relative value (Perisse et al., 2013), the absence of expected shock (Felsenberg et al.,
1068 2018) and learned safety (Jacob and Waddell, 2020).

1069 We found several input pathways that group the PAM DANs into both expected and unforeseen
1070 combinations. For example, the single neurons of clusters 23 (a SEZON) and 24 grouped the
1071 PAM08-md and PAM08-nc (γ 4) DANs with the four subtypes of γ 5 DANs. The cluster 24 neuron
1072 also provides input to a selection of β and β' lobe innervating DANs. Cluster 7 neurons grouped
1073 a different collection of γ 4 and γ 5 with the PAM08-md (γ 3) DANs and most PAM02 (β '2a),
1074 PAM05 (β '2p), PAM06 (β '2m) and PAM13 (β '1ap) and PAM14 (β '1m) DANs. These inputs are
1075 consistent with studies that have implicated the γ 4, γ 5 and β '2 compartments in reward
1076 learning, such as learning reinforced with water and the taste of sugar (Aso and Rubin, 2016;
1077 Burke et al., 2012; Huetteroth et al., 2015; Lin et al., 2014b; Liu et al., 2012; Shyu et al., 2017;
1078 Yamagata et al., 2015). In contrast, clusters 19 and 20 group unique subtypes of γ 5 DANs with
1079 all three α 1 DAN subtypes. Cluster 19 also provides strong input to both types of PAM13 DANs
1080 and the PAM14-can subtype. Prior work has shown that the γ 5 and α 1 DANs are required for
1081 the reinforcement of nutrient-dependent long-term sugar memory (Huetteroth et al., 2015;

1082 Yamagata et al., 2015; Ichinose et al., 2015). A similar complexity of combinatorial inputs is
1083 evident across most of the DAN subtypes in the PAM DAN population.

1084 An unexpected finding was the strong and unique grouping of all subtypes of PAM04 (β_2), two
1085 subtypes of PAM09 (β_1) and the PAM10-vd (β_{1ped}) subtype by the population of neurons in
1086 cluster 8. Two prior studies have shown that artificial activation of β_1 and β_2 DANs together
1087 can form a long-lasting appetitive memory (Perisse et al., 2013; Huetteroth et al., 2015) and
1088 the cluster 8 input suggests that their activity is likely to be genuinely coordinated. The full
1089 importance of these DANs is not currently understood, but our analysis of MBON06 ($\beta_1 > \alpha$)
1090 suggests that appetitive learning via these DANs modulates a key node of the MBON network
1091 (see Discussion).

1092 The PAM11 (α_1) DANs reinforce nutrient-dependent, long-term memory (Huetteroth et al.,
1093 2015; Ichinose et al., 2015; Yamagata et al., 2015). Their connectivity differs from other DAN
1094 cell types in that they receive input from a few clusters of input neurons that are very selective
1095 for PAM11 DANs but do not strongly discriminate between the three α_1 DAN subtypes (Figures
1096 31 and 33). For example, cluster 22 is a single neuron that provides strong, highly selective
1097 input to all three PAM11 subtypes and appears to convey input from the SEZ (Figure 33B).
1098 Clusters 19 and 20 convey information from the LH (Figure 33 E and F). When α_1 DAN input
1099 neurons do show connections to other DANs, this input is much weaker and largely confined
1100 to positive valence DANs (Figure 31).

1101 We uncovered several additional features of the organization of the DAN system. Some input
1102 clusters synapse with multiple cell types, but only with specific DAN subtypes within them
1103 (Figure 36). There are many PAM specific clusters, such as clusters 7, 29, 32 (Figure 36-figure
1104 supplement 1) as well as PPL1 specific clusters, such as clusters 13, 14 and 15 (Figure 36-
1105 figure supplement 2). We also identified several clusters of neurons that innervate subsets of
1106 both PAM and PPL1 DANs (clusters 3, 9, 30, 33, 35; Figure 36 and Figure 36-figure supplement
1107 1). Some clusters, such as 3, 7 and 30, have such dense innervation that their most notable
1108 feature might be the DANs that they do not innervate.

1109 Two discrete classes of dorsal fan-shaped body (FB) neurons make up clusters 10 and 31,
1110 which provide selective input to DANs of opposite valence (Figure 31 and 34). The arbors of
1111 the FB neurons where they synapse to these DANs are of mixed polarity and could simply

1112 serve as a local relay for other inputs. We also note that (Hu et al., 2018) reported that more
1113 ventral layers of the FB respond to electric shock and their artificial activation could substitute
1114 for negative valence reinforcement, but it remains unclear what role, if any, more dorsal FB
1115 layers might play.

1116 Neurons from the SEZ provide a major source of DAN inputs. While studies have shown that
1117 pleasant and unpleasant tastes can reinforce learning by engaging different DAN subsets (Das
1118 et al., 2014; Huetteroth et al., 2015; Kirkhart and Scott, 2015; Masek et al., 2015), the relevant
1119 input pathways are only recently emerging from connectomic studies. A comparison of inputs
1120 to PPL101 (γ 1pedc), PAM01 (γ 5) and PAM05/6 (β '2) DANs identified a set of SEZONs. The
1121 hemibrain dataset provides access to the projections of all SEZONs (although characterizing
1122 their dendritic arbors required identifying the corresponding neurons in the FAFB volume) and
1123 confirms that they are a major source of DAN input (clusters 22-28). Some single neuron
1124 SEZON clusters tend to connect to either exclusively positive valence (clusters 22, 23) or
1125 negative valence (cluster 27) DANs, consistent with them relaying the valence of different
1126 tastants to the MB. Some clusters contain multiple SEZONs (clusters 25, 26 and 28); clusters
1127 25 and 26 innervate only positive valence DANs, while SEZONs in cluster 28 innervate either
1128 PPL101 or DANs of both positive and negative valence.

1129 As with the PPL1 DANs, most neurons providing strong input to PAM DANs do not project from
1130 primary sensory areas in the brain. PAM DANs are therefore also likely to receive highly
1131 processed value-based information. However, as discussed above for PPL101 and previously
1132 noted for the PAM01 (γ 5) and PAM02 (β '2a) DANs (Otto et al., 2020), we found that several
1133 PAM DANs receive significant input from SEZONs. Since blocking some of these neurons has
1134 been shown to impair sugar and/or bitter taste learning (Otto et al., 2020), SEZON input
1135 suggests that taste may provide fairly direct valence-related signals to the DANs. Various
1136 subtypes of PAM01, PAM02, PAM03, PAM08, PAM09, PAM10 and PAM15 DANs all receive
1137 SEZON input, some of which is highly selective. The single SEZON in cluster 22 exclusively
1138 synapses onto the three subtypes of PAM11 (α 1) DANs, whereas another (cluster 27)
1139 synapses selectively with the PPL106 (α 3) DAN. We speculate that the prevalence of SEZON
1140 innervation to the DANs indicates the ecological relevance of evaluating taste for the fly, and
1141 that these very selective pathways to PAM11 (α 1) and PPL106 (α 3) might represent stimuli
1142 that are of unique importance. PAM11 DANs have been previously implicated in the nutrient-

1143 dependent reinforcement of long-term memories. In addition to the recently reported
1144 involvement of SEZONs in sugar learning (Otto et al., 2020), an earlier study demonstrated the
1145 importance of a physical and functional connection between octopaminergic neurons and the
1146 PAM01 (γ 5) and PAM02 (β '2a) DANs (Burke et al., 2012). Also within the top 50 inputs, we
1147 identified synapses from the OA-VPM3 neurons onto PAM01 (γ 5), PAM01 (γ 4) and to a lesser
1148 extent PAM02 (β '2a) DANs. It will be important to understand the relationship between the OA
1149 and SEZON inputs to the rewarding DANs.

1150 Our work provides a comprehensive description of the substructure of DANs, uncovering a
1151 complexity that goes far beyond the previously defined 21 cell types (Aso et al., 2014a).
1152 Understanding the functional significance of this complexity will require more complete
1153 knowledge of the information about the outside world and internal brain state that is conveyed
1154 by the hundreds of neurons that provide input to DANs. Our analyses of the DAN connectivity,
1155 together with what we learned about the segregation of sensory modalities in different classes
1156 of KCs, the selective connectivity of MBONs to KCs, and the discovery of a new class of
1157 MBONs, opens a window onto a much broader and richer landscape of MB circuitry underlying
1158 what a fly might be able to learn, remember and use to guide its behavior.

1159 **Discussion**

1160 The hemibrain dataset we have analyzed contains the most comprehensive survey of the cell
1161 types and connectivity of MB neurons available to date. This connectome allowed us to probe
1162 in fine detail the circuitry underlying canonically proposed functions of the MB, including the
1163 representation of olfactory information by KCs, computation of valence by MBONs, and
1164 reinforcement of associations by DANs. We found patterns in the input to DANs, MBON-to-
1165 DAN and MBON-to-MBON connectivity that suggest how associative learning in the MB can
1166 affect both the acquisition of new information through learning and the expression of previously
1167 learned responses. The connectome also reveals circuitry that supports non-canonical MB
1168 functions, including selective structure in non-olfactory pathways, a network of atypical
1169 MBONs, extensive heterogeneity in DAN inputs, and connections to central brain areas
1170 involved in navigation and movement.

1171 **Advantages and limitations of fly connectomics**

1172 Our analysis of the hemibrain connectome relied heavily on an extensive catalog of previously
1173 identified and genetically isolated cell types and on decades of study illuminating the link
1174 between mushroom body physiology and fly behavior. It is worth emphasizing the
1175 interdependency of anatomy, physiology and behavior as we enter the post-connectomic era
1176 in fly research. Some of the neurons we have described that appear similarly connected may
1177 turn out to have diverse functions due to different physiology (Groschner et al., 2018) and,
1178 conversely, neurons that are morphologically distinct may turn out to have similar functions. In
1179 addition, a set of inputs with high synapse counts might appear, at the connectome level, to
1180 represent a major pathway for activating a particular neuron, but this will not be true if these
1181 inputs rarely fire at the same time. Likewise, a set of highly correlated inputs can be effective
1182 even if their individual synapse counts are modest. Finally, the connectome does not reveal
1183 gap junction connections or identify more distant non-synaptic modulation. These caveats
1184 should be kept in mind when interpreting connectome data (Bargmann and Marder 2013).

1185 **Comparison with the larval MB**

1186 The cell type constituents and circuit motifs of the MB in the adult fly have many similarities
1187 with its precursor at the larval stage of development (Aso et al., 2014a, Eichler et al., 2017,
1188 Takemura et al., 2017, Eschbach et al., 2019, 2020a,b). Both the larval and adult MBs support
1189 associative learning and, in both, PNs from the antennal lobe that convey olfactory information
1190 provide the majority of the sensory input, complemented by thermal, gustatory and visual
1191 sensory information that is segregated into distinct KC populations. However, the multi-layered
1192 organization of non-olfactory inputs in the main and accessory calyces (including integration of
1193 diverse input sources by LVINs) suggests that the KC representation in the adult is more highly
1194 enriched and specialized for non-olfactory sensory features. It is worth noting that the earliest
1195 born types of each of the three main adult KC classes (KC_{γs}, KC_{γd}, KC_{γt}, KC $\alpha\beta$ 'ap1, KC $\alpha\beta$ p)
1196 appear to be specialized for non-olfactory sensory cues, and in most cases their dendrites lie
1197 in the accessory calyces.

1198 In the first instar larval MB, the only larval stage for which a connectome is available (Eichler
1199 et al., 2017), there are roughly 70 mature KCs, which is increased nearly 30-fold in the adult.
1200 This enrichment likely increases odor discrimination and olfactory memory capacity. The larval

1201 MB has only eight compartments in its horizontal and vertical lobes. Although the increase in
1202 the adult to 15 compartments is only about a factor of two, the extent of their DAN modulation
1203 is greatly expanded. The larva has only seven confirmed DANs and five additional cells of
1204 unknown neurotransmitter thought to provide modulatory input, a factor of 15-fold less than the
1205 adult. Whereas each larval KC innervates all 8 compartments, individual adult KCs innervate
1206 only five out of 15 compartments. Therefore the DANs in the larva are capable of modulating
1207 all KCs, whereas in the adult, DANs modulate specific subset of KCs. Subcompartmental
1208 targeting of DAN modulation in the adult increases this difference even more.

1209 MBONs feedback onto DANs and converge onto common downstream targets in both the larva
1210 (Eschbach et al. 2020a,b) and adult, implying some shared computational strategies. However,
1211 the greatly increased DAN complexity in the adult fly and the presence of subcompartmental
1212 organization of DAN axon targets not present in the larva suggest a substantial increase in the
1213 specificity of the learning signals involved in memory formation and raises the possibility of
1214 modality-specific learning signals to complement the multimodal KC representation.

1215 **Sensory input to KCs**

1216 Previous theoretical work has emphasized the advantages of mixing sensory input to the KCs
1217 so that they provide a high-dimensional representation from which MBONs, guided by DAN
1218 modulation, can derive associations between sensory input and stimulus valence (Litwin-
1219 Kumar et al., 2017). The connectome data modifies this viewpoint in two ways. First, although
1220 olfactory input to the KCs is highly mixed, various structural features reduce the dimensionality
1221 of the KC odor representation. A recent analysis of EM data from an adult *Drosophila* MB
1222 identified groups of PNs thought to represent food odors that are preferentially sampled by
1223 certain KCs (Zheng et al., 2020). Consistent with this observation, our analysis revealed
1224 subtype-specific biases in PN sampling by KCs, including an overrepresentation of specific
1225 glomeruli by α/β and α'/β' KCs. These biases, as well as other structural features, appear to
1226 arise from the stereotyped arrangement of PN axons within the calyx and their local sampling
1227 by KCs. This may reflect a developmental strategy by which the KC representation is organized
1228 to preferentially represent particular PN combinations. Further analyses of KC connectomes
1229 across hemispheres and animals, as well as experimental studies, will help evaluate the impact
1230 of this structure.

1231 The hemibrain connectome also revealed a second, more dramatic, structural feature of
1232 sensory input to the MB: non-olfactory input streams corresponding to visual and thermo-hygro
1233 sensation are strongly segregated. This organization may reflect the nature of stimulus-valence
1234 associations experienced by flies. When valence depends on a specific combination of stimulus
1235 attributes, such as binding to particular sets of olfactory receptors, MBONs need to be able to
1236 sample those combinations to successfully identify the stimulus. However, if different sensory
1237 modalities can be used separately to identify valence, mixing may not be necessary. For
1238 example, either the visual appearance of an object or its odor may individually be sufficient to
1239 identify it as a food source (for a discussion of multi-sensory learning in flies, see Guo and Guo,
1240 2005). We asked whether there is an advantage in having separate modality-specific sensory
1241 pathways, as seen in the connectome data, when valences can be decomposed in this way.

1242 To address this question we considered a model in which KC input is divided into two groups,
1243 visual and olfactory (Figure 38A). In one version of the model (“shared KC population”), all KCs
1244 receive sparse random input from both types of PNs, corresponding to a high degree of mixing
1245 across modalities. In the other (“separate KC populations”), half of the KCs receive sparse
1246 random input exclusively from visual PNs and half only from olfactory PNs, corresponding to
1247 no cross-modal mixing. We define two tasks that differ in the way valences are defined. In the
1248 first (factorizable) version of the task, each olfactory stimulus and each visual stimulus is
1249 assigned a positive or neutral subvalence, and the net valence of the combined stimulus is
1250 positive if either of these components is positive (olfactory OR visual). In the second
1251 (unfactorizable) version, a valence is randomly assigned independently to each
1252 olfactory+visual stimulus pair. We evaluated the ability of a model MBON, acting as a linear
1253 readout, to determine valence from these two different KC configurations. Separate modality-
1254 specific KC populations are indeed beneficial when the valence can be identified from either
1255 one modality or the other (the 'factorizable' case in Figure 38B). Dedicating different KC
1256 subtypes to distinct sensory modalities allows the predictive value of each modality to be
1257 learned separately. This result suggests that the divisions into KCs specialized for visual,
1258 thermo/hygro and olfactory signals may reflect a property of natural valences across these
1259 modalities.

1260 **Sub-compartmental modulation by DANs**

1261 On the basis of light-level studies, DAN modulation of KC-to-MBON synapses has been
1262 considered to operate at the resolution of MB compartments. However, taken with other recent
1263 studies (Lee et al., 2020; Otto et al., 2020), the morphology and connectivity data indicate that
1264 functionally distinct PAM-DAN subtypes operate within a MB compartment. DAN subtypes
1265 receive different inputs and likely modulate different KC-MBON synapses within a
1266 compartment.

1267 A prior analysis showed that PAM01-fb DANs were required to reinforce the absence of
1268 expected shock during aversive memory extinction, whereas a different set of γ 5 DANs were
1269 needed for learning with sugar reinforcement (Otto et al., 2020). It is conceivable that another
1270 γ 5 DAN subtype is required for male flies to learn courtship rejection (Keleman et al., 2012).
1271 The connectome data revealed DAN subtypes in every compartment that is innervated by PAM
1272 DANs.

1273 The γ 3 compartment provides an interesting example of subcompartmental targeting of
1274 modulation by DANs and of KC input onto MBONs (Figure 39). There are two subtypes of
1275 PAM DANs and three types of MBONs in the γ 3 compartment. MBON09 and MBON30 primarily
1276 receive olfactory information from γ m KCs whereas MBON33 primarily receives visual
1277 information from γ d KCs. PAM12-dd and PAM12-md DANs appear to modulate KC inputs to
1278 MBON09/MBON30 or MBON33, respectively. Although existing driver lines do not separate
1279 the dd and md subtypes, PAM- γ 3 DAN activity is suppressed by sugar (Yamagata et al., 2016)
1280 and activated by electric shock (Jacob and Waddell, 2020). We found that PAM12-dd DANs
1281 share input with PPL1 DANs conveying punishment signals, while PAM12-md DANs are co-
1282 wired with PAM08 (γ 4) DANs conveying reward signals. Thus, synaptic transmission from two
1283 sets of modality-specific KCs to different MBONs can be independently modulated by DANs
1284 signaling different valences, all within a single compartment.

1285 To explore the implications of DAN modulation that is specific to sensory modality, we extended
1286 the model presented above (Figure 38A) by including two DANs, one conveying the visual
1287 component of valence and the other the olfactory component (Figure 38C). KCs were divided
1288 into visual and olfactory modalities, and we considered two configurations for DAN modulation,

1289 one, “shared reward signal”, that is compartment-wide and non-specific, and the other,
1290 “separate reward signals”, in which each DAN only induces plasticity onto KC synapses
1291 matching its own modality. This latter case models a set of DANs that affect synapses from
1292 visual KCs onto the MBON and another set that affect olfactory synapses (alternatively, it could
1293 model two MBONs in different compartments that are modulated independently and converge
1294 onto a common target). We find that, when KCs are divided into separate populations and
1295 separate modalities can be used to identify valence, it is beneficial to modulate the pathways
1296 individually (Figure 38D).

1297 **Functional implications of DAN input heterogeneity and MBON feedback to DANs**

1298 Our analysis revealed that DANs receive very heterogeneous inputs but, nonetheless, some
1299 DANs both within and across compartments often share common input. This combination of
1300 heterogeneity and commonality provides many ways of functionally combining different DAN
1301 subtypes. For example, we expect that it allows DANs to encode many different combinations
1302 of stimuli, actions and events in a state-dependent manner and to transmit this information to
1303 specific loci within the MB network.

1304 In addition to heterogeneous inputs from a variety of brain regions, the DAN network receives
1305 a complex arrangement of within and across compartment monosynaptic input from a variety
1306 of MBONs, using both excitatory and inhibitory neurotransmitters. We found that nearly all MB
1307 compartments contain at least one direct within-compartment MBON-DAN feedback
1308 connection. MBON feedback onto DANs allows previously learned associations that modify
1309 MBON activity to affect future learning. MBONs that feedback onto the same DANs that
1310 modulate them could, if the result of learning is reduced DAN activity, prevent excess plasticity
1311 for an already learned association. In cases where MBON activity excites the DAN, the self-
1312 feedback motif could assure that learning does not stop until the MBON has been completely
1313 silenced. More generally, MBON inputs to DANs imply that dopaminergic signals themselves
1314 reflect learned knowledge and the actions it generates. This could, in turn, allow MBON
1315 modulation of DAN activity to support a number of learning paradigms beyond pure classical
1316 conditioning, including extinction, second-order conditioning, operant conditioning and
1317 reinforcement learning.

1318 Flies can perform second-order conditioning, in which a stimulus that comes to be associated
1319 with reinforcement may itself act as a pseudo-reinforcement when associated with other stimuli
1320 (Tabone and de Belle, 2011). This computational motif of learning the value of sensory states
1321 and using the inferred value as a surrogate reinforcement to guide behavioral learning is the
1322 core principle behind a class of machine learning techniques known as actor-critic algorithms.
1323 These algorithms consist of two modules: the “actor,” whose job is to map sensory inputs to
1324 behavioral outputs and the “critic,” whose job is to map sensory inputs to their inferred values
1325 and provide these values as a learning signal for the actor. In the mammalian basal ganglia,
1326 the dorsal and ventral striatum, the latter of which strongly influences the activity of dopamine
1327 neurons in areas including VTA, have been proposed to represent actor and critic modules,
1328 respectively. In the mushroom body, this perspective suggests a possible additional ‘critic’
1329 function for some MBONs beyond their known ‘actor’ role in directly driving behaviors.
1330 Consistent with this view, activation of individual MBONs can excite DANs in other
1331 compartments (Cohn et al., 2015; Felsenberg et al., 2017). We found strong direct
1332 monosynaptic connections between some MBONs and DANs in other compartments.
1333 Functional studies will be needed to determine which MBONs, if any, participate in an actor-
1334 critic arrangement, and which circuit mechanisms—for example, release from inhibition, or
1335 reduction of excitation—are at work.

1336 Another potential role of cross-compartment MBON-DAN feedback is to gate the learning of
1337 certain associations so that the learning is contingent on other associations having already
1338 been formed. Such a mechanism could support forms of memory consolidation in which long-
1339 term memories are only stored after repeated exposure to a stimulus and an associated reward
1340 or punishment. Prior studies have linked plasticity in the $\gamma 1$ and $\gamma 2$ compartments to short-term
1341 aversive memory (Aso et al., 2012; Hige et al., 2015; Perisse et al., 2016; Sejourne et al., 2011)
1342 and plasticity in the $\alpha 2$ and $\alpha 3$ compartments to long-term aversive memory (Aso and Rubin,
1343 2016; Awata et al., 2019; Jacob and Waddell, 2020; Pai et al., 2013; Sejourne et al., 2011).
1344 The cross-compartmental MBON to DAN connections we observed suggest an underlying
1345 circuit mechanism for this “transfer” of short to long term memory. Aversion drives PPL101
1346 ($\gamma 1pedc$) and depresses the conditioned odor-drive to the GABAergic MBON11 ($\gamma 1pedc > \alpha/\beta$).
1347 MBON11 is strongly connected with PPL1- $\gamma 1pedc$, but only much more weakly connected with
1348 PPL105 and PPL106. Depression of MBON11 will therefore release the PPL105 and PPL106

1349 DANs from MBON11-mediated inhibition, increasing their activity in response to the
1350 conditioned odor and making them more responsive during subsequent trials. The net result is
1351 that short-term aversive learning by MBON11 ($\gamma 1pedc > \alpha/\beta$) promotes long-term learning in
1352 MBON18 ($\alpha 2sc$) and MBON14 ($\alpha 3$) by releasing the inhibition on the dopamine neurons that
1353 innervate the $\alpha 2$ and $\alpha 3$ compartments (Sejourne et al., 2011; Jacob and Waddell, 2020).
1354 Indeed pairing inactivation of MBON11 with odor presentation can form an aversive memory
1355 that requires output from PPL1-DANs (Ueoka et al., 2017) and optogenetic stimulation of
1356 MBON11 during later trials of odor-shock conditioning impairs long-term memory formation
1357 (Awata et al., 2019).

1358 Cross-compartment MBON-DAN feedback may also enable context-dependent valence
1359 associations, such as the temporary association of positive valence with neutral stimuli when
1360 a fly is repeatedly exposed to aversive conditions. Multiple, spaced aversive conditioning trials
1361 were recently shown to form, in addition to an aversive memory for the shock-paired odor, a
1362 slowly emerging attraction, a 'safety' memory, for a second odor that was presented over the
1363 same training period without shock (Jacob and Waddell, 2020). MBON09 ($\gamma 3\beta'1$) appears to
1364 play a critical role in the formation of this safety memory. The synapses from KCs conveying
1365 the shock-paired odor are depressed in that the portion of MBON09's dendrite that arborizes
1366 in $\gamma 3$, while the synapses from KCs conveying the safety odor are depressed in its $\beta'1$ arbor.
1367 These combined modulations should gradually release downstream neurons from MBON09
1368 feedforward inhibition, consistent with the proposed mechanism for PAM13/14 ($\beta'1$) and
1369 PAM05/06 ($\beta'2m$ and $\beta'2p$) DANs becoming more responsive to the safe odor (Jacob and
1370 Waddell, 2020). The connectome data revealed that MBON09 is directly connected to the
1371 PAM13/14 ($\beta'1ap$) and PAM05 ($\beta'2p$) DANs, consistent with release from inhibition underlying
1372 the delayed encoding of safety.

1373 DANs also make direct connections with MBONs in each MB compartment, and optogenetic
1374 activation of PAM11 DANs can directly excite MBON07 with slow dynamics (Takemura et al.,
1375 2017). The excitation of the MBON by the DAN during memory retrieval can temporally
1376 suppress expression of the memory, since the memory is conveyed to the rest of the brain by
1377 the lowered activity of the downstream MBON. But the memory itself, which is stored by
1378 depressed KC to MBON synapses, is not extinguished (Takemura et al., 2017; Schleyer et al.,

1379 2020). This observation raises the possibility that MBON-DAN feedback may play a role in
1380 regulating memory expression (Krashes et al., 2009; Senapati et al., 2019).

1381 **MBON-MBON interactions**

1382 Feedforward MBON-MBON connections were postulated, based on behavioral and light
1383 microscopic anatomical observations, to propagate local plasticity between compartments (Aso
1384 2014a, b). The GABAergic MBON11 is poised to play a key role in such propagation as it is
1385 connected with 17 other MBONs (at a threshold of 10 synapses). Thus local depression of KC-
1386 MBON11 synapses by the shock responsive PPL1- γ 1pedc DAN would be expected to result
1387 in disinhibition of MBONs in other compartments. Indeed enhanced CS+ responses of
1388 MBON01 and MBON03 after odor-shock conditioning have been ascribed to release from
1389 MBON11 inhibition (Owald et al., 2015; Perisse et al., 2016; Felsenberg et al., 2018). The
1390 consequence of releasing other strongly connected MBONs (MBON07, MBON14 and
1391 MBON29) from MBON11 inhibition awaits future study. As discussed above, MBON11 is also
1392 connected to DANs innervating its cognate compartment and to DANs innervating other
1393 compartments. MBON11 may therefore coordinate MBON network activity via both direct and
1394 indirect mechanisms. We also found analogous feedforward inhibitory connections from
1395 MBON09 (γ 3 β '1) to MBON01 and MBON03. Aversive learning will therefore reduce both
1396 MBON11- and MBON09-mediated inhibition of these MBONs, which would then further skew
1397 the MBON network towards directing avoidance of the previously punished odor (Figure 40).

1398 Disinhibition likely also plays an important role in appetitive memory (Figure 41). The
1399 connectivity of MBON06 (β 1 $>$ α) revealed here indicates that local plasticity in the β 1
1400 compartment can propagate to other MBONs. Similar to MBON11, MBON06 is directly
1401 connected with nine other MBONs with a threshold of 10 synapses. MBON06 gradually
1402 increases its response to repeated odor exposure (Hattori et al., 2017) and odor-evoked
1403 responses of β 1 DANs vary with metabolic state (Siju et al. 2020). More compellingly, artificially
1404 triggering PAM09 (β 1) DANs can assign appetitive valence to odors (Perisse et al., 2013;
1405 Huetteroth et al., 2015; Aso and Rubin, 2016). However, the role of MBON06 in appetitive
1406 memory and how the PAM09 (β 1) DANs modulate KC synapses to MBON06 have not been
1407 further investigated. The glutamatergic MBON06 (β 1 $>$ α) makes a large number of reciprocal
1408 axoaxonic connections with the GABAergic MBON11 (Takemura et al., 2017), whose activation

1409 favors approach (Aso et al., 2014b; Perisse et al., 2016). This reciprocal network motif and the
1410 positive sign of behavior resulting from $\beta 1$ DAN-driven memory suggests that MBON06
1411 released glutamate is likely to be inhibitory to MBON11 and its other downstream targets.
1412 MBON06 also makes twice as many connections onto the glutamatergic MBON07 and the
1413 cholinergic MBON14 as does MBON11. MBON14 ($\alpha 3$) and MBON07 ($\alpha 1$) have established
1414 roles in appetitive memory (Placais et al., 2013; Huetteroth et al., 2015; Yamagata et al., 2015;
1415 Ichinose et al., 2015; Widmer et al., 2018). Assuming that PAM09 ($\beta 1$) DANs encode appetitive
1416 memory by depressing synapses from odor-specific KCs onto MBON06 ($\beta 1 > \alpha$), MBON06
1417 suppression will release the feedforward inhibition of MBON06 onto MBON07 ($\alpha 1$), freeing it to
1418 participate in driving the PAM11-aad ($\alpha 1$) DANs (Ichinose et al., 2015). Release of MBON06
1419 inhibition should also simultaneously potentiate the responses of MBON14 ($\alpha 3$) to the
1420 conditioned odor (Placais et al., 2013). Lastly, releasing the strong inhibition from MBON06
1421 frees MBON11 to provide weaker inhibition that would further favor odor-driven approach
1422 (Perisse et al., 2016; Sayin et al., 2019).

1423 Aversive learning will also alter the function of the MBON06:MBON11 network motif (Figure
1424 40). Aversive reinforcement through the PPL101 ($\gamma 1pedc$) DAN depresses KC-MBON11
1425 connections. This depression releases MBON06 from MBON11-mediated suppression and
1426 allows MBON06 to then suppress output through MBON07 and MBON11, further favoring odor-
1427 driven avoidance.

1428 **The influence of internal state in the network**

1429 Several studies have described the influence of internal states such as hunger and thirst on
1430 the function and physiology of the MB. In essence, states appear to modulate the DAN-MBON
1431 network so that the fly preferentially engages in the pursuit of its greatest need (Senapati et al.,
1432 2019). Since our current knowledge suggests these deprivation states employ volume release
1433 of modulatory peptides or monoamines to control specific DANs and their downstream MBONs
1434 (Krashes et al., 2009; Lin et al., 2014b; Lewis et al., 2015; Tsao et al., 2018; Sayin et al., 2019;
1435 Siju et al., 2020), the connectome we have analyzed does not provide a complete description
1436 of this circuit. Nevertheless, direct connectivity does provide some interesting new insight
1437 concerning hunger (Figure 41) and thirst-dependent control.

1438 The MBON06 ($\beta 1 > \alpha$):MBON11 ($\gamma 1 \text{pedc} > \alpha / \beta$) cross-inhibitory network motif is likely to be
1439 relevant for the dependence of learning and memory expression on hunger state (Figure 41).
1440 PPL101 ($\gamma 1 \text{pedc}$) DANs and MBON11 ($\gamma 1 \text{pedc} > \alpha / \beta$) are sensitive to nutrient/satiety status,
1441 with MBON11 being more responsive in hungry flies (Krashes et al., 2009; Placais and Preat,
1442 2013; Perisse et al., 2016; Pavlowsky et al., 2018). Therefore, the hungry state favors the
1443 activity of the MBONs that are normally repressed by MBON06.

1444 Thirst-dependent seeking of water vapor requires the activity of DANs innervating the $\beta'2$
1445 compartment (Lin et al., 2014b). Our current work shows that these DANs are likely to directly
1446 modulate thermo/hygrosensory KCs. In addition, a recent study showed that thirst-dependent
1447 expression of water memory required peptidergic suppression of the activity of both the
1448 PPL103- $\gamma 2\alpha'1$ and PAM02 ($\beta'2a$) DANs (Senapati et al., 2019). Interestingly, blocking the
1449 PAM02 ($\beta'2a$) DANs released memory expression in water-sated flies whereas blocking the
1450 PPL103- $\gamma 2\alpha'1$ DANs had no effect. However, if the PPL103- $\gamma 2\alpha'1$ DANs were blocked together
1451 with PAM02 ($\beta'2a$) they further facilitated water memory expression. The connectome suggests
1452 circuit mechanisms that could reconcile these observations: MBON12 ($\gamma 2\alpha'1$) provides strong
1453 cholinergic input to the PAM02 ($\beta'2a$) DANs, suggesting that PPL103- $\gamma 2\alpha'1$ DANs might
1454 facilitate water memory expression by suppressing MBON12's excitatory input onto PAM02
1455 ($\beta'2a$) DANs.

1456 **A possible role for MB output in the control of movement**

1457 A role for the MB in guiding locomotion and navigation in ants and other insects has been
1458 proposed (Ardin et al., 2016; Collett and Collett, 2018; Kamhi et al., 2020; Kim et al., 2019;
1459 Mizunami et al., 1998; Le Möel F, Wystrach A. 2020; Paulk and Gronenberg, 2008; Sun et al.,
1460 2020). The strong and direct connections we observed from the majority of MBONs to the CX,
1461 the fly's navigation and locomotion control center, provide one circuit path for the MB to exert
1462 influence on motor behaviors. Discovering how this input is utilized by the CX will require
1463 additional experimental work.

1464 Optogenetic activation of *Drosophila* MBONs can promote attraction or avoidance by
1465 influencing turning at the border between regions with and without stimulating light (Aso et al
1466 2014b). The effect of MBON activation is additive: coactivation of positive-valence MBONs
1467 produced stronger attraction, whereas coactivation of positive and negative-valence MBONs

1468 cancelled each other out. Because the fly needs to balance the outputs of different
1469 compartments, we expect that those downstream neurons that integrate inputs from multiple
1470 MBONs will have a privileged role in motor control.

1471 The activity of some DANs has been shown to correlate with motor activity (Berry et al., 2015;
1472 Cohn et al, 2015), and the optogenetic activation of PAM- β '2 or PPL1- α 3 DANs can attract
1473 flies, indicating that DAN activity can itself in some circumstances drive motor behavior. The
1474 circuit mechanisms generating the correlation between DAN activity and motor behavior remain
1475 to be discovered. Downstream targets of MBONs provide extensive input to DANs, and we
1476 found that neurons downstream of multiple MBONs are twice as likely as other MBON targets
1477 to provide such direct input to DANs.

1478 We also discovered a direct pathway mediated by atypical MBONs that connects to the
1479 descending neurons that control turning, an observation that provides additional support for the
1480 importance of the MB in the control of movement. The atypical MBONs that connect directly to
1481 the descending steering system, MBON26, MBON27, MBON31 and MBON32, appear to be
1482 among the most integrative neurons in the MB system in the sense that they combine direct
1483 KC input from the MB compartments with both input from many other MBONs and non-MB
1484 input. At the level of the descending neurons, the highly processed signals from these MBONs
1485 are combined with inputs from many other sources, including the central complex, to affect a
1486 decision to turn. This high degree of integration presumably reflects the complexity and
1487 importance of this decision, with many factors involved that might act individually or in
1488 combination.

1489 Visual input to the MB is over-represented in the output to the descending neurons,
1490 predominantly through MBON27. Short- and long-term learning based on features in a visual
1491 scene has been reported to involve the CX (Liu et al., 2006; Neuser et al., 2008). Plasticity in
1492 the CX enables visual feature input from the sky and surrounding scenery to be mapped flexibly
1493 onto the fly's internal compass (Fisher et al., 2019; Kim et al., 2019). The visual input conveyed
1494 to the MB and, presumably, the learning at the synapses between visual KCs and MBON27,
1495 may be of lower resolution, encoding broader features such as color and contrast (Guo, 2005;
1496 Tang, 2001; Zhang et al., 2007). An early study demonstrated that the MB is dispensable for
1497 flying *Drosophila* to learn shapes but that it is required for them to generalize their learning if

1498 the visual context changes between training and testing (Liu et al., 1999). Memory of visual
1499 features and the ability to generalize context could allow visual landmarks to help guide
1500 navigation either through the CX or by directly influencing descending neurons. The
1501 thermo/hygrosensory features conveyed by MBON26 could play a similar role, as could the
1502 large amount of odor-related information present in this MBON output pathway.

1503 **Concluding remarks**

1504 The MB has an evolutionarily-conserved circuit architecture and uses evolutionarily-conserved
1505 molecular mechanisms of synaptic plasticity. The dense connectome analysed in this report
1506 has uncovered many unanticipated circuit motifs and suggested potential circuit mechanisms
1507 that now need to be explored experimentally. In *Drosophila*, we currently have access to many
1508 of the required tools such as cell-type-specific driver lines, genetically encoded sensors and
1509 microscopy methods to observe whole brain neuronal activity and fine ultrastructure. These
1510 features make the fly an excellent system in which to study many general issues in
1511 neuroscience, including: the functional diversity of dopaminergic neurons that carry distributed
1512 reinforcement signals, the interactions between parallel memory systems, and memory-guided
1513 action selection, as well as the mechanisms underlying cell-type-specific plasticity rules,
1514 memory consolidation, and the influence of internal state. We expect studies of the MB to
1515 provide insight into general principles used for cognitive functions across the animal kingdom.

1516 As mentioned in the introduction, the MB shares many features with the vertebrate cerebellum,
1517 and our results should be informative for studies of the cerebellum proper as well as other
1518 cerebellum-like structures such as the dorsal cochlear nucleus and the electrosensory lobe of
1519 electric fish. A distinctive feature of these systems, and of the MB, is that learning is driven by
1520 a particular mechanism; for example DAN modulation in the MB or complex spiking driven by
1521 climbing fiber input in the cerebellum. Studies of learning in cortical circuits have traditionally
1522 focused on Hebbian forms of learning driven by the ongoing input and output activity of a
1523 neuron. However, recent results from both hippocampal (Bittner et al., 2017) and cortical
1524 (Gambino et al., 2014; Lacefield et al., 2019; Larkum, 2013) circuits have stressed the
1525 importance of plasticity that is driven by dendritic plateau potentials or bursts that resemble the
1526 distinct learning events seen in cerebellar and MB circuits. Thus, the form of plasticity seen in

1527 the MB and its control by output and modulatory circuits may inform studies of learning in the
1528 cerebral cortex as well.

1529 **Materials and Methods**

1530 **Connectivity and Morphological Data**

1531 The analyses reported in this paper were all based on the hemibrain:v1.1 dataset (Scheffer et
1532 al., 2020). Analyses were done by querying this dataset using the neuPrint user interface or,
1533 for more complex queries, by directly querying the neuPrint backend Neo4J graph database
1534 (Clements et al., 2020). In some analyses and diagrams, a threshold was applied so as to only
1535 consider connections representing more than a certain number or percentage of synapses.
1536 Any such thresholds are stated in the figure legends; otherwise, all connections were included
1537 in the analysis. Each individual neuron has a unique numerical identifier (generally 8 to 10
1538 digits) that refers to that neuron as seen in this dataset. Neurons were also grouped into
1539 putative cell types and given names as described in Scheffer et al. (2020) and we use those
1540 v1.1 names here. Even though most of the cell types in the MB were already known, we still
1541 found a few new cell types, which we named using established naming schemes. We further
1542 refined morphological groupings with relevant information on connectivity (see below).

1543 Each neuron's unique identifier is permanent, while we expect cell type classifications and
1544 neuron names to be continuously updated in response to new biological information. For that
1545 reason, we present the unique identifiers for all the neurons we discuss, either by stating them
1546 in the main text, figures or figure legends, or by providing links in the figure legends to the
1547 appropriate data in neuPrint. The version of the dataset that we used for the analyses reported
1548 here will be archived under the name "hemibrain:v1.1" and will remain available in neuPrint,
1549 even after additional data releases are made. As described in Scheffer et al., (2020), in addition
1550 to the "named neurons" (whose status is indicated as "Traced" in neuPrint) there are also small
1551 fragments that, while assigned a unique identifier, are not connected to any named neuron.
1552 These small fragments were excluded from our analysis.

1553

1554 **Morphological Clustering**

1555 Our overall method of cell type classification is described in Scheffer et al., (2020) and was
1556 applied to generate Figures 3 and 6.

1557 Kenyon Cell Morphological Clustering. Analysis of Kenyon cell morphologies (Figures 4 and 5)
1558 was carried out in R using the natverse toolkit (Bates et al., 2020a). Briefly, skeletons were
1559 downloaded from neuprint.janelia.org using the neuprint read neurons function from the
1560 neuprint package, which healed any gaps in the skeleton and rerooted on the soma. When
1561 required, neurons were simplified to one major branch using nat::simplify_neuron. Prior to
1562 NBLAST, neurons were scaled to units of microns, resampled to 1 μm step size and converted
1563 to dotprops format with $k=5$ neighbors. In order to reduce the weight given to the many fine
1564 branches present in EM reconstructions, nat::prune_twigs was applied with twig_length=2.
1565 Standard NBLAST clustering was then carried out using the nat.nblast package as previously
1566 described (Costa et al., 2016). For KC cell typing, we carried out a stepwise manual NBLAST
1567 clustering followed by manual review, which resulted in 17 reassignments. These manual
1568 reassignments were almost exclusively cases in which a KC more closely resembled one
1569 $\text{KC}\alpha/\beta$ subtype in the vertical lobe and either the subsequent or previously generated subtype
1570 in the medial lobe, possibly because it was born during the developmental transition from
1571 generation of $\text{KC}\alpha/\beta\text{s}$ to $\text{KC}\alpha/\beta\text{m}$ or from $\text{KC}\alpha/\beta\text{m}$ to $\text{KC}\alpha/\beta\text{c}$.

1572 Morphological Clustering of DANs. DAN cell types reported in the `hemibrain:v1.1` were further
1573 divided by morphological clustering into subtypes using NBLAST and manual inspection as
1574 described in Otto et al., (2020). To generate the results presented in Figures 28, 30 and 31,
1575 the same steps as described above, but no simplification was carried out, and nat::prune_twigs
1576 was applied with twig_length=5 - a combination that was manually reviewed to preserve subtle
1577 differences in dendrites and axons. For Figures 28 and Figure 28-figure supplement 1,
1578 hierarchical clustering was performed on DANs of each type/compartments using a wrapper
1579 function for base R clustering functions with nat.nblast (nat.blast::nhclust), taking Euclidean
1580 distance matrices of similarity scores, with average linkage clustering criterion. The number of
1581 clusters and the content was manually reviewed.

1582 Clustering by morphology of the top dendritic inputs to each DAN subtype (Figures 31-37) was
1583 performed as follows: The 50 input neurons with the most input synapses to each DAN subtype

1584 was performed using hierarchical clustering with average linkage criterion on all-by-all NBLAST
1585 similarity scores, which were obtained as described above. In addition, a multi-step approach
1586 was needed because of the morphological diversity of the upstream population (see Otto et al.,
1587 2020). Only designated right hemisphere dendritic input neurons were considered; MB intrinsic
1588 neurons (MBONs, KCs, DPM, and APL) and unnamed neuron fragments were excluded.
1589 Before clustering, neurons were simplified by `nat::prune_twigs` with `twig length = 5`. Input
1590 neurons were initially split into 25 coarse clusters, largely representative of neuropil of origin.
1591 These primary clusters were then individually sub-clustered to yield 235 clusters using an
1592 iterative manual review process, taking into account within cluster differences in connectivity.
1593 Thirty-five representative clusters were selected and used for the analyses shown in Figures
1594 31 - 37.

1595 **Connectivity analysis**

1596 Connectivity-based clustering: Neurons with practically indistinguishable shapes but with
1597 different connectivity patterns can often be split into connectivity subtypes within a morphology
1598 type. To generate the cell type assignments reported in Scheffer et al., (2020) we made
1599 extensive use of a tool for cell type clustering based on neuron connectivity, called CBLAST.
1600 In an iterative process, using neuron morphology as a template, neurons were regrouped after
1601 more careful examination of neuron projection patterns and their connections. This is especially
1602 useful in the case of a dataset like ours, in which noise and missing data make it difficult to rely
1603 solely on connectivity to find a good partitioning automatically. CBLAST clusters neurons
1604 together using a similarity feature score defined by how the neuron distributes inputs and
1605 outputs to different neuron types. In some cases, this readily exposes incompleteness (for
1606 example, due to the finite size of the volume) in some neurons. Based on these interactions,
1607 we made decisions and refined the clusters manually, iterating until further changes are not
1608 observed. CBLAST usually generates clusters that are consistent with the morphological
1609 groupings of the neurons, with CBLAST often suggesting new sub-groupings as intended.

1610 In a number of instances we obtained high-level groupings of neurons based on their input or
1611 output connectivity and without regard to morphology: Figure 10-figure supplement 3; Figure
1612 11-figure supplements 2, 4 and 5; Figure 13-figure supplements 1 and 2; Figure 16; Figure 16-
1613 figure supplements 1 and 3; Figure 17; Figure 17-figure supplements 1; Figure 27; Figure 27-

1614 figure supplements 1 and 2. This was achieved by performing spectral clustering (Shi and
1615 Malik, 2000) on the input (or output) connectivity of a set of neurons using cosine similarity as
1616 the clustering metric. Spectral clustering is particularly appropriate in cases where there is no
1617 clear hierarchical structure to the data but there are clearly defined groupings. Spectral
1618 clustering requires specifying the number of clusters in advance -- in some cases, we specified
1619 this value manually, and in others, we automatically determined it by choosing the value that
1620 yielded the optimal silhouette score, a measure of clustering quality. All other parameters of
1621 the implementation were taken from the default values used by the SpectralClustering method
1622 in Python's scikit-learn package.

1623 For the hierarchical clustering by input connectivity of PAM DANs shown in Figure 28, KC-DAN
1624 connectivity was excluded to prevent bias. Before clustering the number of synapses between
1625 input neurons and each DAN was normalized by the remaining input to that DAN (minus KC
1626 input). Hierarchical clustering with the r-base function hclust was performed for DANs of each
1627 type/compartment using the Manhattan distance between upstream connectivity profiles of
1628 DANs with Ward's clustering criterion.

1629 For determination of the DAN to KC and DAN to MBON connectivity shown in Figure 30 and
1630 Figure 30-figure supplements 2 and 3, synapse counts between subtypes of DANs and
1631 subclasses of KCs were normalized by the total synapse count between DANs and that KC
1632 type, and then thresholded at 0.5%. Synapse counts between DAN subtypes of the right
1633 hemisphere and MBONs with dendrites in the right hemisphere were normalized by the total
1634 number of synapses connections made to that MBON type, and then thresholded at 0.1%.

1635 For producing the connectivity data shown in Figures 31-37, connectivity information was
1636 retrieved from neuPrint with the neuprintr function neuprint_connection_table (natverse) for
1637 each morphological cluster of upstream neurons to each DAN subtype innervating the right
1638 MB. Only synapses in the right hemisphere were used due to incomplete connectivity in the
1639 left hemisphere and to prevent bias between PPL and PAM DANs. Connectivity to DAN
1640 subtypes was thresholded as indicated in the figure legends.

1641 Comparison of clustering based on morphology and connectivity (Figure 28): Tanglegrams
1642 were generated to facilitate visual comparison of dendrograms of morphology- and
1643 connectivity-based clustering using the tanglegram function of the dendextend package (see

1644 Otto et al., 2020). Dendrogram layouts were determined to minimize edge crossing using
1645 `dendextend::untangle` with `method="step2side"` (Galili, 2015). The Mantel test (Legendre and
1646 Legendre 2012) implemented in `vegan::mantel` (<https://github.com/vegandevs/vegan>) was
1647 used to evaluate the similarity of morphology- and connectivity- based clustering. Pearson's
1648 correlation between the distance matrices of these two observed datasets was calculated, then
1649 one of the matrices was shuffled all possible ways or at least 10^7 times and each event tested
1650 for correlation with the observed data. The number of events where the correlation was higher
1651 than between the two original datasets was divided by the amount of comparisons to create a
1652 p-value. When p-values were lower than the significance level, the null model of independence
1653 between the two feature spaces was rejected.

1654 **Calculation of multi-step effective connectivity**

1655 In several analyses, we computed the "effective" connectivity through multi-synaptic pathways
1656 between a set of source and target neurons: Figure 10-figure supplement 2; Figure 11-figure
1657 supplement 1; Figure 26-figure supplement 1 and 2; Figure 27-figure supplement 3. Although
1658 our procedure generalizes to pathways of any length, we only performed it for two-step (or
1659 "one-hop") pathways. To do so, we determined the set of interneurons either postsynaptic to
1660 the source population or presynaptic to the target population. Starting with the matrices of
1661 source-interneuron connectivity and interneuron-target connectivity, we normalized each so
1662 that the sum of inputs to each postsynaptic cell summed to 1. Then we multiplied the two
1663 matrices to yield an estimate of effective source-target connectivity. This procedure reflects
1664 the assumption that an output synapse from an interneuron conveys information about its
1665 inputs to varying degrees, which are proportional to the number of input synapses coming from
1666 each input.

1667 **Data presentation**

1668 The 3D renderings of neurons presented in the Figures were generated using the visualization
1669 tools of NeuTu (Zhao et al., 2018a); grey-scale images of EM data were taken from NeuTu.
1670 Annotations were added using Adobe Illustrator. Color depth MIP masks of MCFO or FAFB
1671 skeletons were generated using the `ColorMIP_Mask_Search` plugin for Fiji
1672 (https://github.com/JaneliaSciComp/ColorMIP_Mask_Search) (Otsuna et al., 2018).
1673 Cytoscape (cytoscape.org) was used to produce the node layout of connectivity diagrams of

1674 connections between neurons, which were then edited in Adobe Illustrator. Videos were
1675 produced using Blender (blender.org) and a set of custom Python scripts written by Philip
1676 Hubbard (Hubbard, 2020). Narration was recorded using Camtasia (techsmith.com) and text
1677 and narration were added to videos using Adobe Premiere Pro.

1678 **Declaration of interests**

1679 None.

1680 **Acknowledgements**

1681 This work was supported by the Howard Hughes Medical Institute, by the MRC (MC-
1682 U105188491 to GSXEJ), by the Wellcome Trust (203261/Z/16/Z to GSXEJ, GMR and SW), by

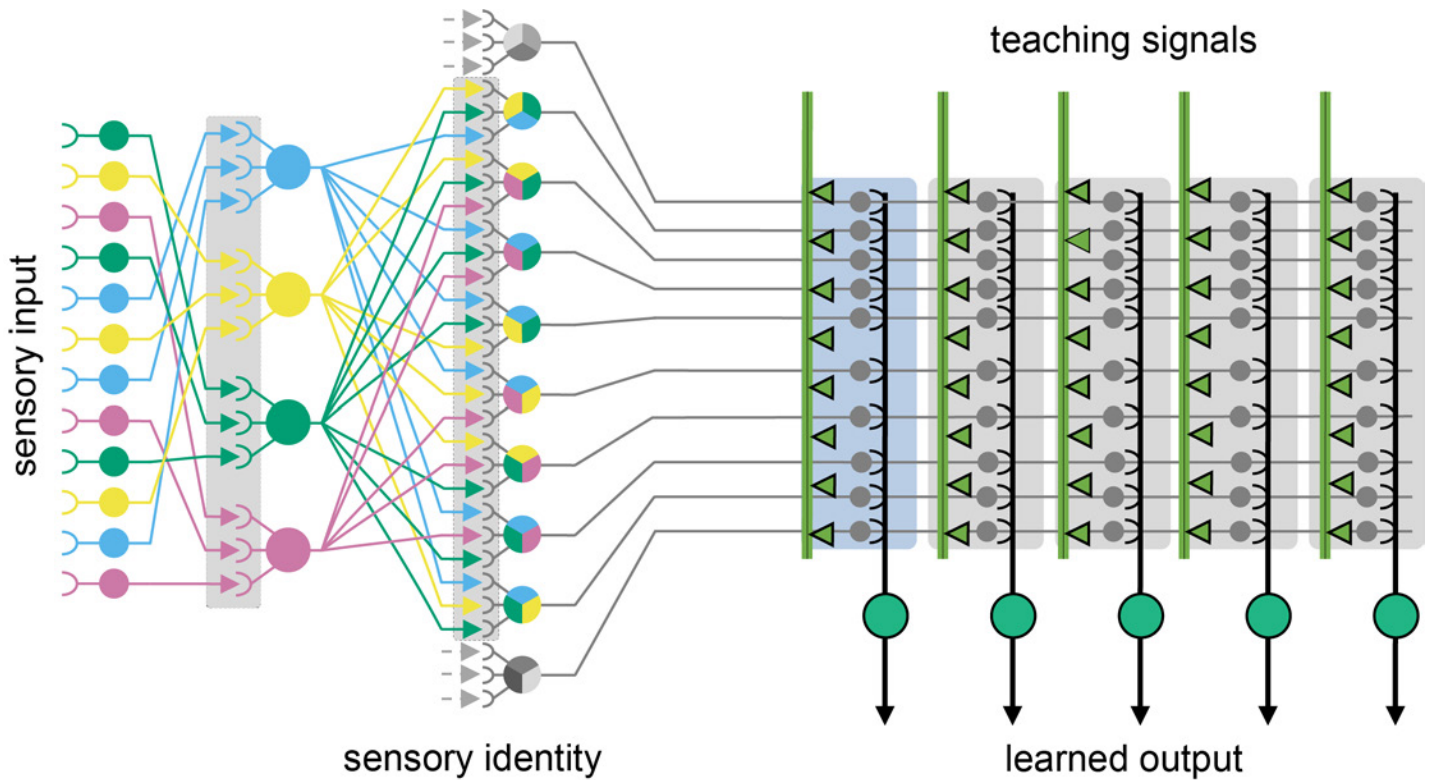

Figure 1. The shared circuit architecture of the mushroom body and the cerebellum.

In both the insect MB and vertebrate cerebellum sensory information is represented by sparse activity in parallel axonal fibers — Kenyon cells (KCs) in the MB and granule cells (GC) in the cerebellum (reviewed in Modi et al., 2020). In general, each KC or GC has claw-like dendrites that integrate sensory input from a small number of neurons, called projection neurons in insects and mossy fibers in vertebrates. In the MB, teaching signals are provided by dopaminergic neurons (DANs) and in the cerebellum by climbing fibers. Learned output is conveyed to the rest of the brain from the MB lobes by MB output neurons (MBONs) or, from the cerebellar cortex, by Purkinje cells. The arbors of the DANs and MBONs overlap in the MB lobes and define a series of 15 compartments (Aso et al., 2014a; Gao et al., 2019); Figure 2; Video 2); similarly, overlap between the arbors of climbing fibers and Purkinje cells define zones along the GC parallel fibers.

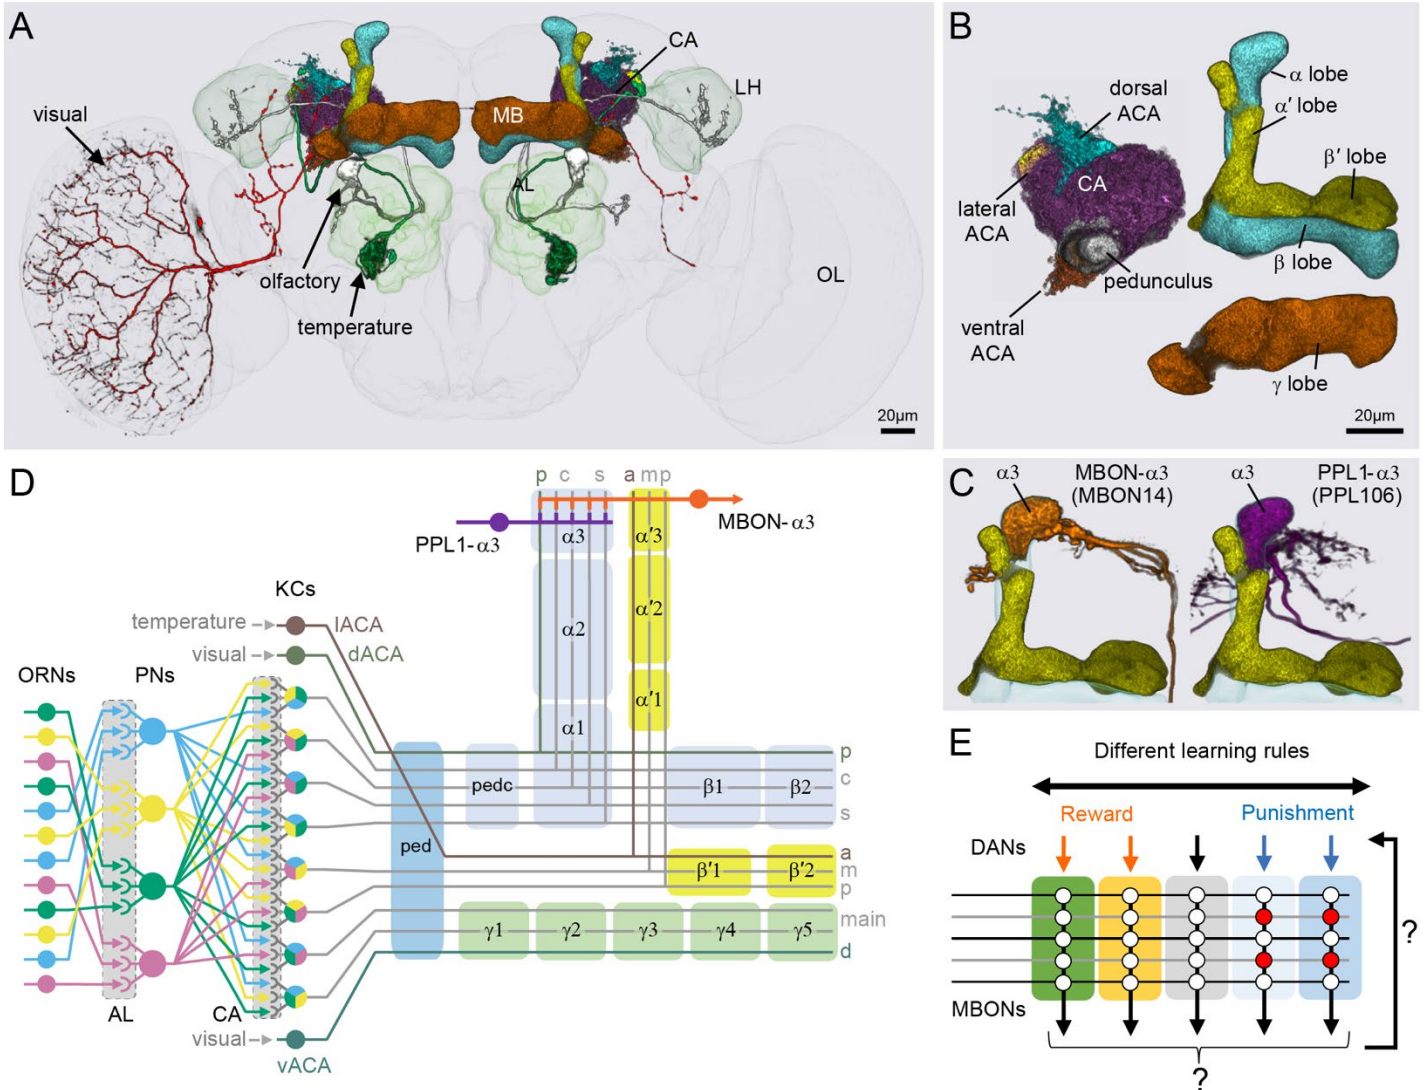

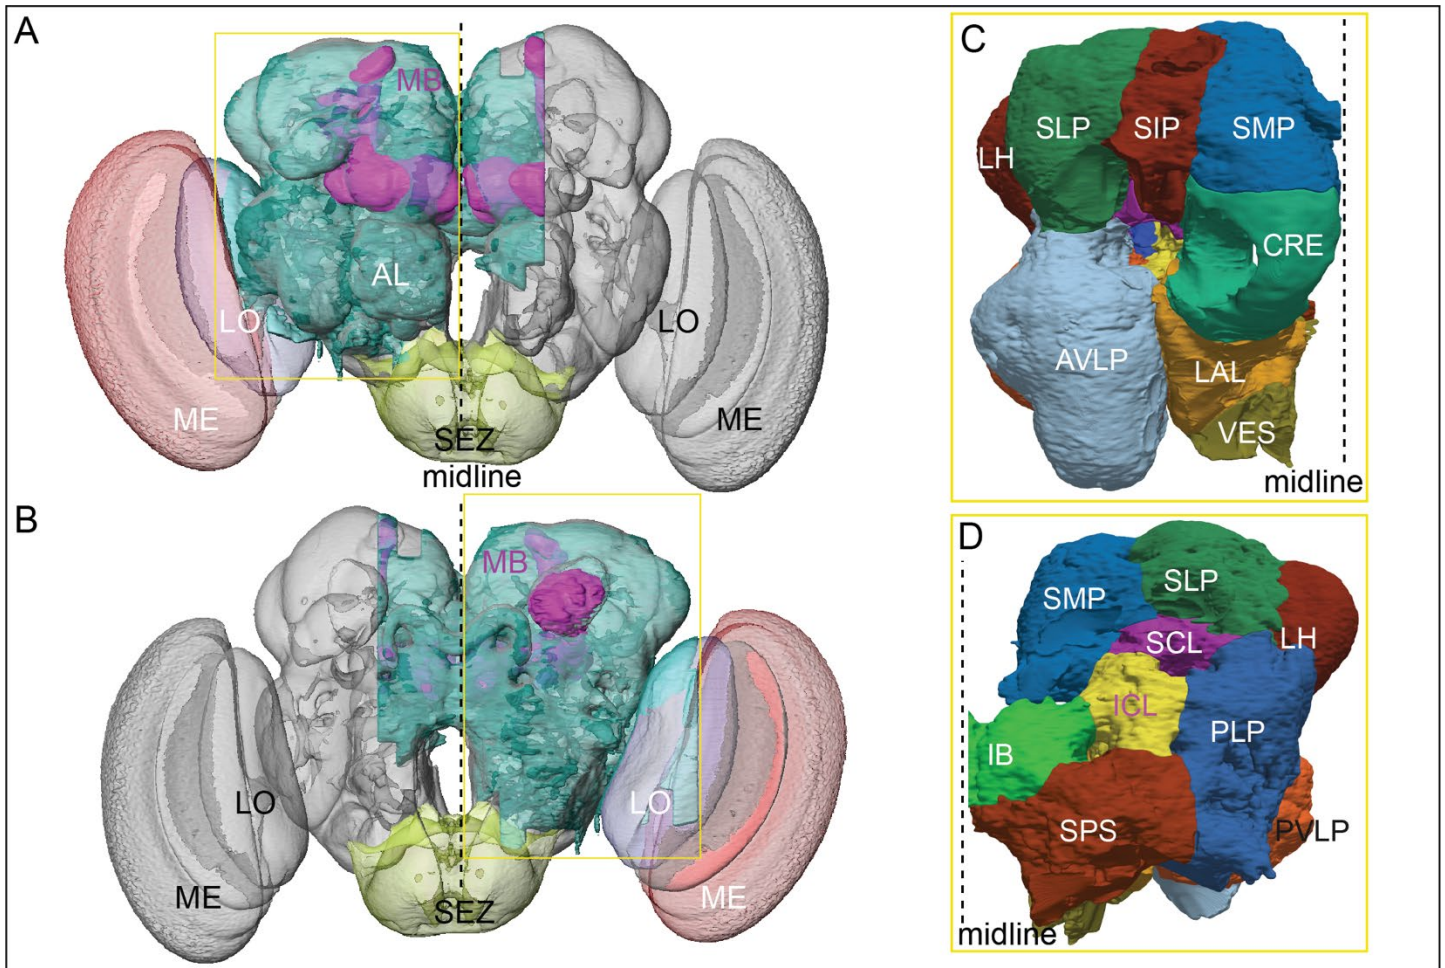

Figure 2. Anatomy of the adult *Drosophila* MB.

Diagram of structure and information flow in the MB. (A) An image of the brain showing subregions of the MB (see panel B for more detail) and examples of the sensory pathways that provide information to the KCs. Projection neurons (PNs) from the 51 olfactory glomeruli of the antennal lobe (AL) extend projection neurons (PN) to the calyx (CA) of the MB and the lateral horn (LH). A total of 126 PNs, using a threshold of 25 synapses, innervate the CA and 3 innervate the IACA. Six olfactory PNs from the DL3 glomerulus are shown (white). Also shown is a visual projection neuron, aMe12 (red) that conveys information from the optic lobe (OL) to the ventral accessory calyx (vACA) and a thermosensory projection neuron (green) that conveys cold temperature information from arista sensory neurons in glomerulus VP3 to the IACA; the positions of the accessory calyces are shown in (B). See Video 1 for additional details. (B) Subregions within the MB. The γ lobe, CA, and pedunculus are displayed separately from other lobes; their normal positions are as shown in panel A. Color-coding is as in panel A. (C) The MB output neuron (MBON14) whose dendrites fill the $\alpha 3$ compartment at the tip of the vertical lobe is shown along with the dopaminergic neuron (PPL106), whose axonal terminals lie in the same compartment. See Video 2 for more detailed examples of the structure of a compartment. (D) A schematic representation of the key cellular components and information flow during processing of sensory inputs to the MB. Olfactory receptor neurons (ORNs) expressing the same odorant receptor converge onto a single glomerulus in the AL. A small number (generally 3 - 4) of PNs from each of the 51 olfactory glomeruli innervate the MB, where they synapse on the dendrites of the ~ 2000 Kenyon

cells (KCs) in a globular structure, the CA. Each KC exhibits, on average, 6 dendritic 'claws', and each claw is innervated by a single PN. The axons of the KCs project in parallel anteriorly through the pedunculus (ped) to the lobes, where KCs synapse onto the dendrites of MB output neurons (MBONs). KCs can be categorized into three major classes α/β , α'/β' , and γ , based on their projection patterns in the lobes (Crittenden et al., 1998). The β , β' , and γ lobes constitute the medial lobes (also known as horizontal lobes), while the α and α' lobes constitute the vertical lobes. These lobes are separately wrapped by ensheathing glia (Awasaki et al., 2008). The α/β and α'/β' neurons bifurcate at the anterior end of the ped (pedc) and project to both the medial and vertical lobes (Lee et al., 1999). The γ neurons project only to the medial lobe. Dendrites of MBONs and terminals of modulatory dopaminergic neurons (DANs) intersect the longitudinal axis of the KC axon bundle, forming 15 subdomains or compartments, five each in the α/β , α'/β' , and γ lobes (numbered α_1 , α_2 , and α_3 for the compartments in the α lobe from proximal to distal and similarly for the other lobes; Aso et al., 2014a; Tanaka et al., 2008). Additionally, one MBON and one DAN innervate the core of the distal pedunculus (pedc) intersecting the α/β KCs. In the current work, we further classified KCs into 14 types, 10 main types and 4 unusual embryonic born KCs, named $KC\gamma s1-s4$ (see Figure 3); the main KC types have their dendrites in the main calyx, with the following exceptions: The dendrites of γd KCs form the ventral accessory calyx (vACA; Aso et al., 2009; Butcher et al., 2012); those of the $\alpha/\beta p$ KCs form the dorsal accessory calyx (dACA; Lin et al., 2007; Tanaka et al., 2008); and the dendrites of a subset of α'/β' cells form the lateral accessory calyx (lACA) (Marin et al., 2020; Yagi et al., 2016). These accessory calyces receive non-olfactory input (Tanaka et al., 2008). Different KCs occupy distinct layers in the lobes as indicated (p: posterior; c: core; s: surface; a: anterior; m: middle; main and d: dorsal). Some MB extrinsic neurons extend processes only to a specific layer within a compartment. (E) Individual compartments serve as parallel units of memory formation (see Aso and Rubin, 2016). Reward or punishment is conveyed by dopaminergic neurons, and the coincidence of dopamine release with activity of a KC modifies the strength of that KC's synapses onto the MBONs in that compartment. The circuit structure by which those MBONs combine their outputs to influence behavior and provide feedback to dopaminergic neurons are investigated in this paper.

Figure 2-figure supplement 1. The extent of the hemibrain volume and key to brain area nomenclature.

(A) The portion of the central brain (light blue) that was imaged and reconstructed to generate the hemibrain volume (Scheffer et al., 2020) is superimposed on a frontal view of a grayscale representation of the entire *Drosophila* brain (JRC 2018 unisex template; Bogovic et al., 2019). The mushroom body (MB) is shown in purple. The midline is indicated by the dotted black line. The brain areas LO, ME and SEZ, which largely lie outside the hemibrain, are labeled. (B) The same structures viewed from the posterior side of the brain. (C,D) Labeled brain regions in the area indicated by the yellow boxes in panels A and B, respectively. The table shows the abbreviations and full names for brain regions discussed in this paper. See Scheffer et al., (2020) for details.

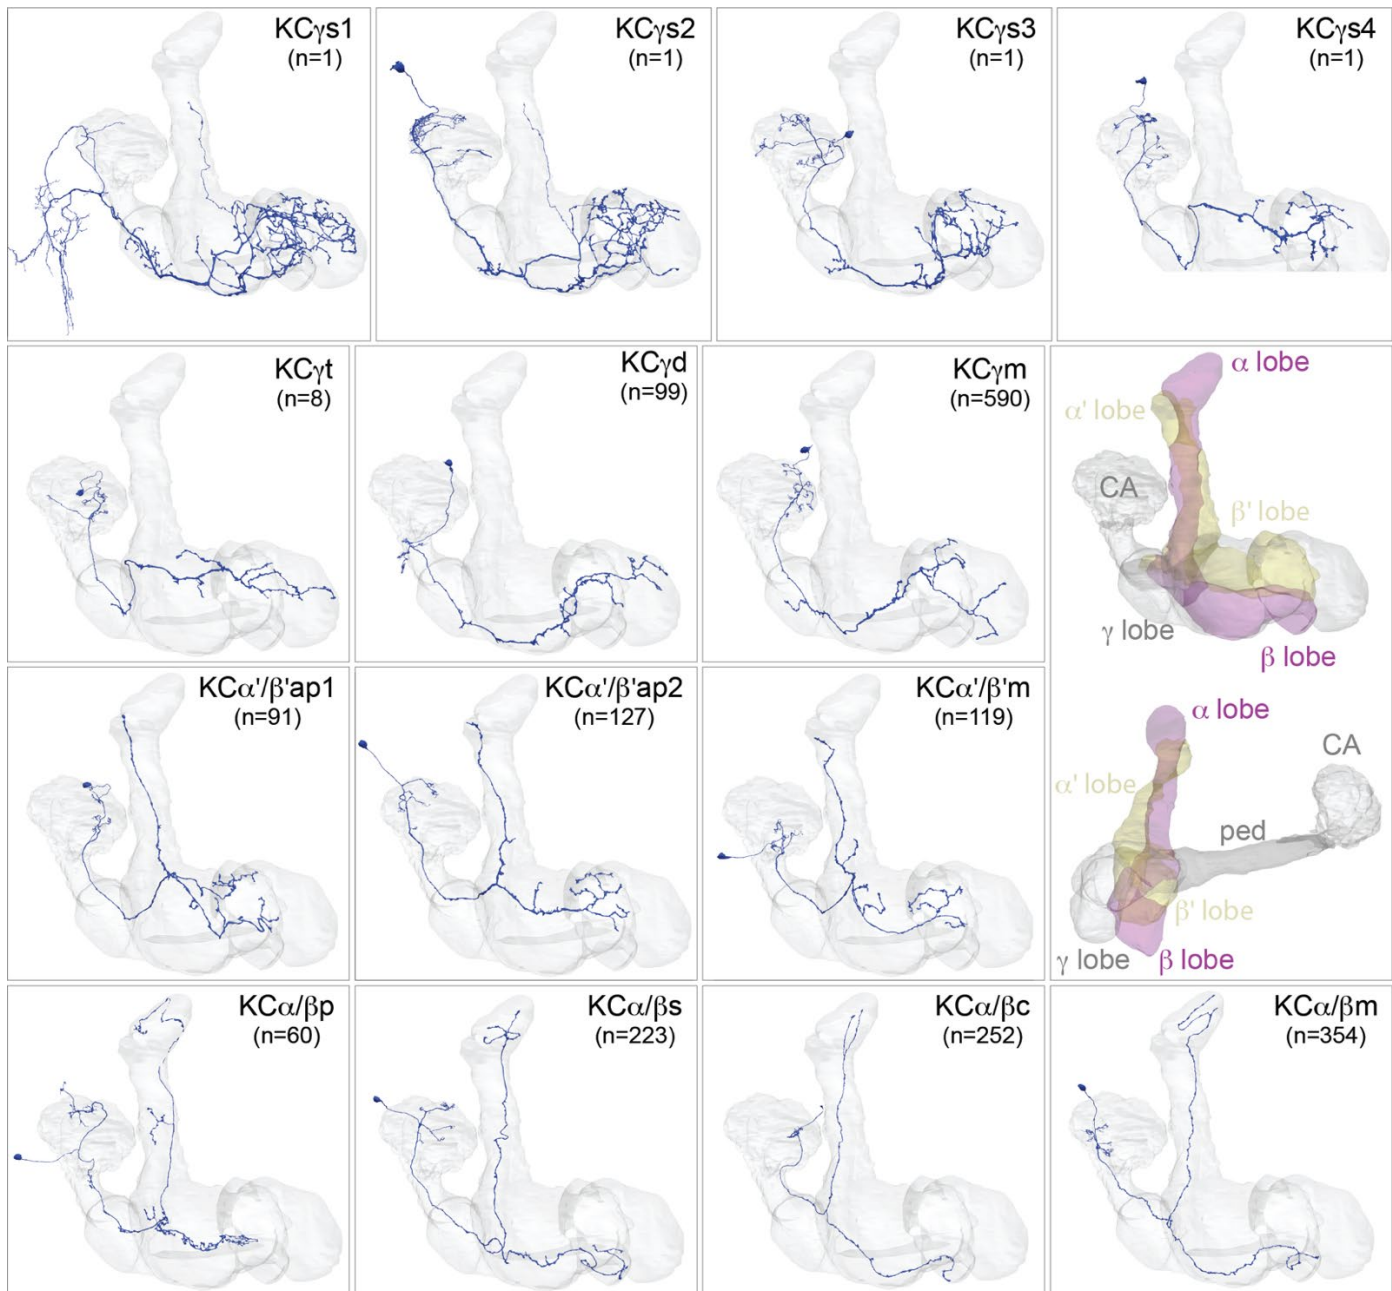

Figure 3. Kenyon cells

Each panel shows a representative neuron of the indicated KC subtype together with the outline of the MB lobes and CA in grey, in a perspective view from an oblique angle to better display neuronal morphology. The insert on the right provides a key to the position of the individual lobes, the pedunculus (ped) and CA; the upper image presents the same view as KC subtype panels and the lower image shows a rotated view to better visualize the ped and CA. The numbers (n=) indicate the number of cells that comprise each KC subtype in this animal; the number of KCs is known to vary between animals (reviewed in Aso et al., 2009). Several of the KC subtypes are defined here for the first time, based on morphological clustering, as described in Figure 4. Although reconstruction of 78 KC α / β was incomplete in the CA as a consequence of a small area of reduced image quality, it did not affect morphological clustering, which was based on simplified axonal skeletons. More information about each of these cell types is shown in Video 3. Additional intrinsic and extrinsic neurons with processes in the MB are shown in Figure 3-figure supplement 1.

Figure 3-figure supplement 1. APL, DPM, SIFamide, OA neurons and other modulatory neurons.

Neuronal morphologies are shown. (A) The anterior posterior lateral neuron, [APL](#), innervates the entire MB (Video 4). APL is GABAergic and provides negative feedback important for sparse coding of odor identities (Lin et al., 2014a; Liu and Davis, 2009; Papadopoulou et al., 2011; Tanaka et al., 2008). (B) The dorsal paired medial neuron, [DPM](#), innervates the lobes in their entirety and the distal pedunculus (Video 4). The DPM neuron has been proposed to use the neuropeptide amnesiac (Waddell et al., 2000), serotonin (Lee et al., 2011) and GABA (Haynes et al., 2015) as neurotransmitters and has been reported to be gap-junctionally coupled to APL (Wu et al., 2011). DPM has an important role in memory consolidation (Haynes et al., 2015; Keene et al., 2006; Pitman et al., 2011; Yu et al., 2005). The connectivity between DPM and APL and other neurons within the α lobe was described by Takemura et al. (2017), and our observations for the full MB are consistent with that description. (C) Two neurons that express the neuropeptide SIFamide, [SIFa](#), are shown here and in Video 5 (Park et al., 2014; Verleyen et al., 2004). (D-F) Three types of neurons that express the neurotransmitter octopamine (OA) are shown here and in Video 5 (Busch et al. 2009; Aso et al. 2014a): (D) [OA-VPM3](#), (E) [OA-VPM4](#) and (F) [OA-VUMa2](#). (G) [PPL201](#) is a PPL2ab cluster dopaminergic neuron with axonal terminals in the CA, lateral horn (LH) and SLP; it has also been referred to as PPL2a (Mao and Davis, 2009; Tanaka et al., 2008; Zheng et al., 2018). In the CA, 16% of $KC\alpha/\beta$ and 25% of $KC\alpha'/\beta'$ and $KC\gamma$ m receives synapses from PPL201; however, KCs devoted to visual information are only very sparsely innervated (5% of $KC\alpha/\beta$ p and 3% of $KC\gamma$ d). The dendrites of this neuron are in the SMP and CRE. (H) Two GABAergic [MB-C1](#) neurons (shown in different colors) innervate the LH and CA (Mao and Davis, 2009; Tanaka et al., 2008; Zheng et al., 2018). (I) The serotonergic [CSD](#) neuron innervates the AL, LH and CA (Dacks et al., 2009). In panels G-I, yellow dots indicate presynaptic sites (sites where these neurons make synapses onto other neurons) and dark grey dots indicate postsynaptic sites (sites where these neurons receive input from other neurons).

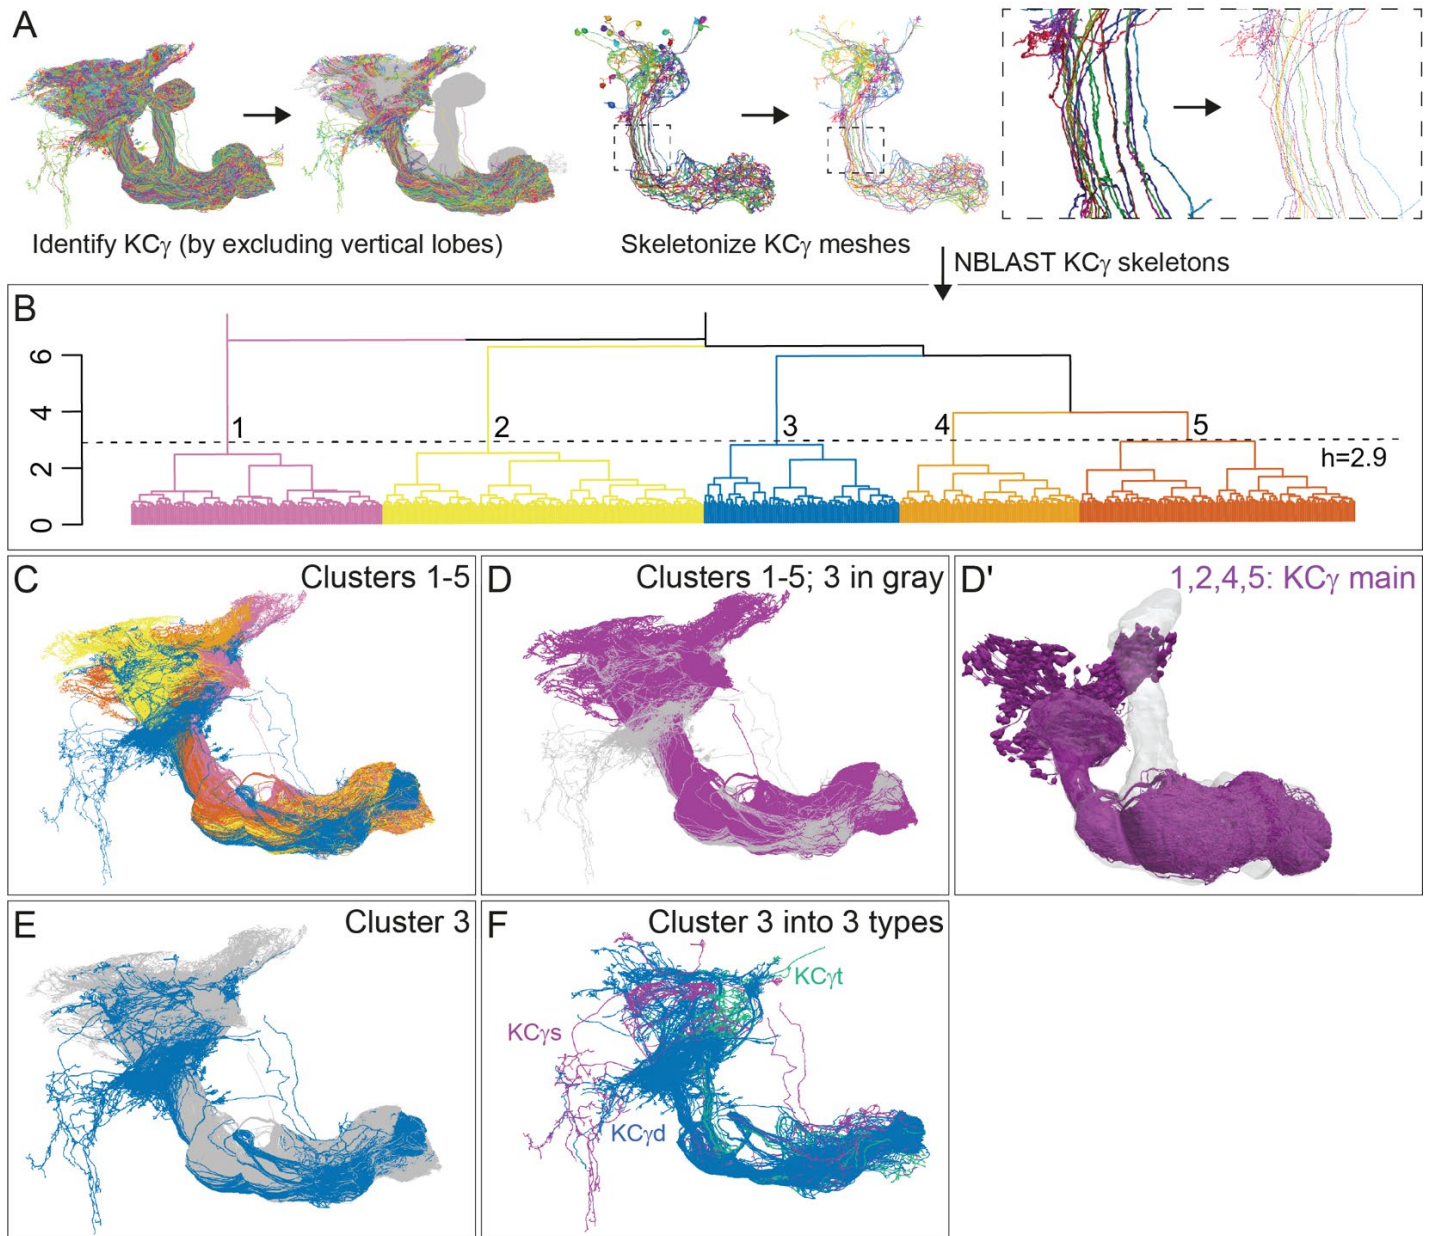

Figure 4. Morphological hierarchical clustering reveals previously unrecognized KC subtypes.

(A) KC_{γ} typing workflow, using KC_{γ} as an example. All γ KCs in the population of annotated KCs were identified by excluding all KCs with axons in the vertical lobes. The space filling morphologies of γ KCs were converted to skeletons (enlarged in the dashed box for clarity) and then NBLAST all-by-all neuron clustering (Costa et al., 2016) was used to reveal morphological groups. (B) Morphological hierarchical clustering of KC_{γ} based on NBLAST scores is shown, cut at height 2.9 (dashed line), which produces 5 clusters. (C) KC_{γ} skeletons of those five clusters are shown, color-coded as in (B). (D) KC_{γ} skeletons in clusters 1, 2, 4 and 5, which includes all 590 $KC_{\gamma}m$, are shown in magenta; cluster 3 is shown in grey. (D') Space filling morphologies of $KC_{\gamma}m$ (clusters 1, 2, 4 and 5) shown in magenta with the MB in grey. (E) KC_{γ} skeletons in cluster 3 (blue), which includes all $KC_{\gamma}d$, and clusters 1-2 and 4-5 (grey), which correspond to the $KC_{\gamma}m$ type are shown. (F) KC_{γ} skeletons from cluster 3, cut at height 1.3, which produces 6 sub-clusters corresponding to three color-coded subtypes: green, 3.1 (eight $KC_{\gamma}t$); magenta, 3.2 (four $KC_{\gamma}s$); and blue, 3.3-3.6 (99 $KC_{\gamma}d$); see Figure 4-figure supplement 1 for details).

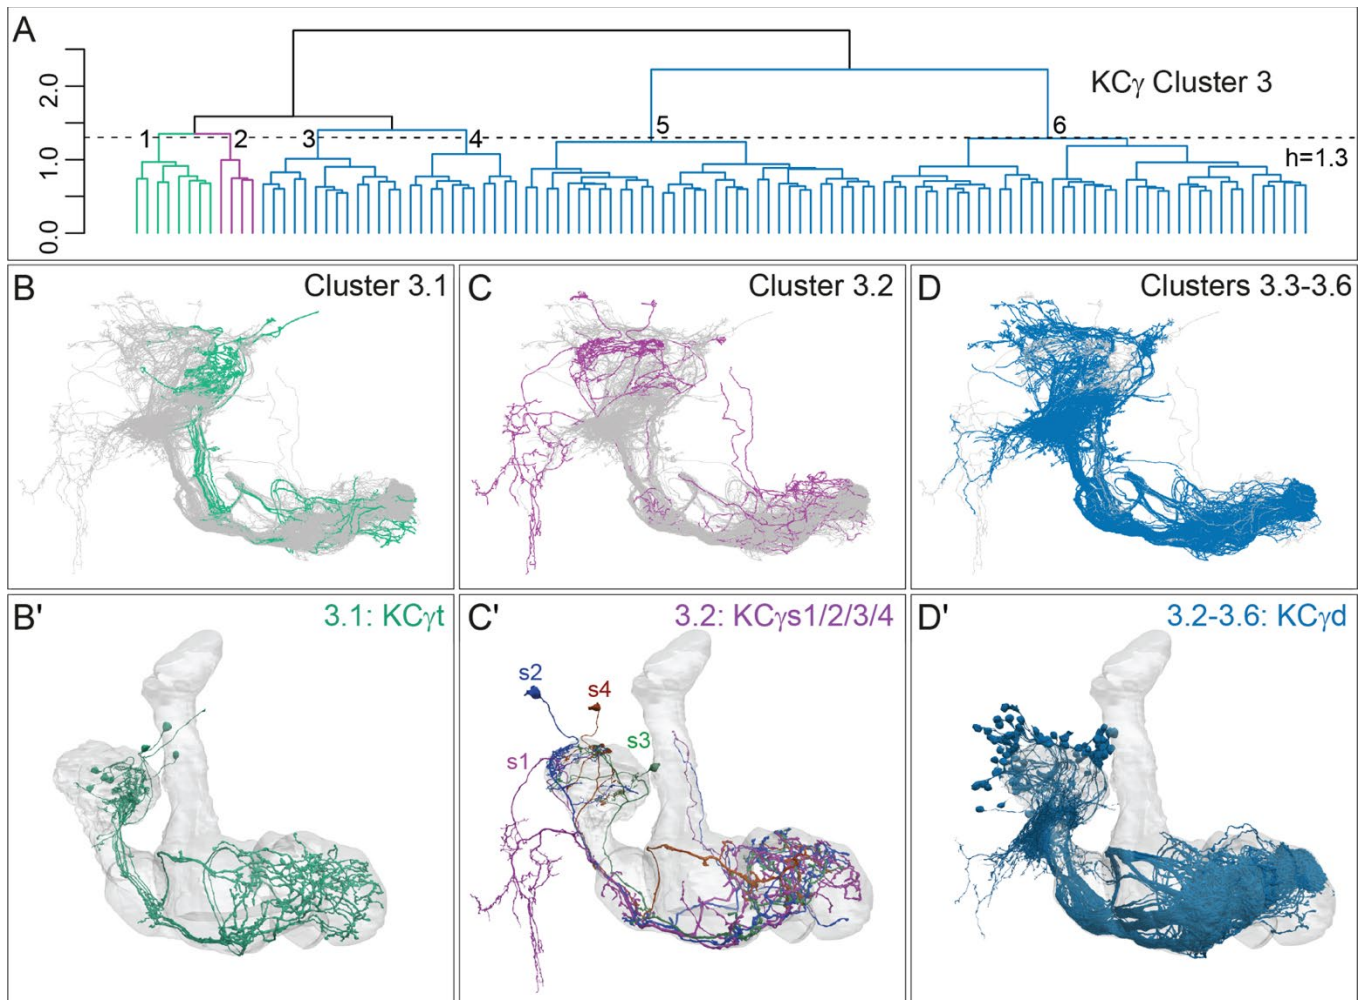

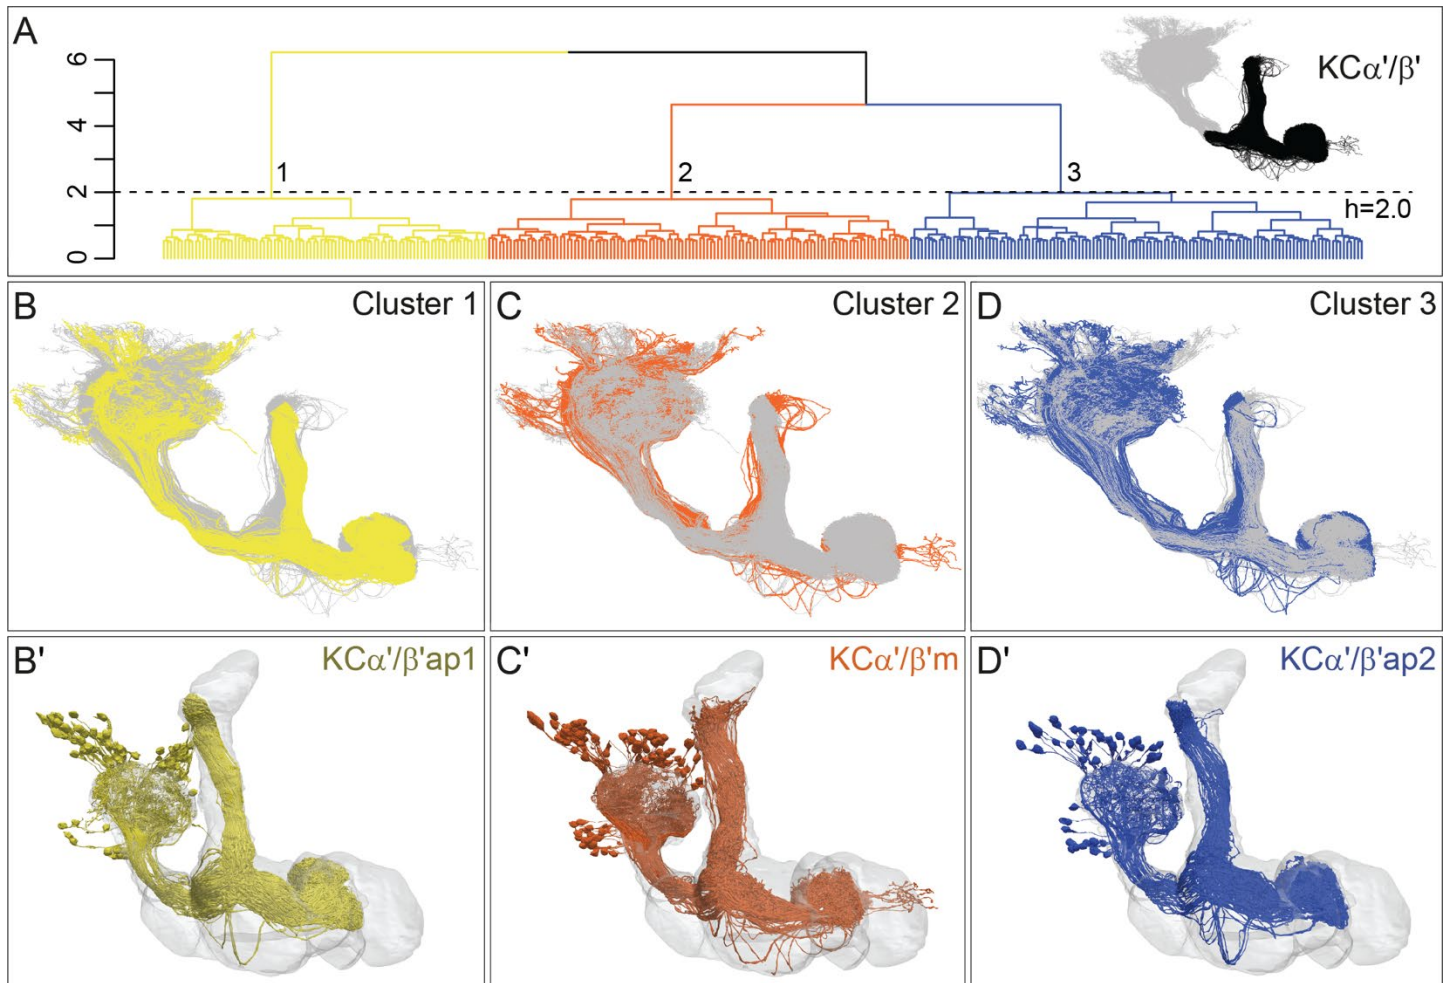

Figure 4-figure supplement 1. Successive rounds of whole neuron morphological hierarchical clustering reveal novel KC_{γ} subtypes.

(A) Morphological hierarchical clustering based on NBLAST scores for all-by-all comparison of KC_{γ} cluster 3 (from Figure 4B) cut at height 1.3 (dashed line); 6 sub-clusters are produced corresponding to 3 neuronal subtypes. (B) $KC_{\gamma t}$ skeletons (cluster 3.1) shown in green, with remaining KC_{γ} found in cluster 3 shown in grey. (B') Space-filling morphologies of the same $KC_{\gamma t}$ with the MB shown in grey. The eight $KC_{\gamma t}$ neurons innervate the anterior of the CA, where most thermo/hygro-sensory PNs project. (C) $KC_{\gamma s}$ skeletons in cluster 3.2 shown in magenta, with remaining KC_{γ} found in cluster 3 shown in grey. (C') Space-filling morphologies of the four unique neurons of subtype $KC_{\gamma s}$, $KC_{\gamma s1/2/3/4}$, shown in magenta, dark blue, green, rust, respectively with the MB shown in grey. Each $KC_{\gamma s}$ likely derives from a different neuroblast. $KC_{\gamma s1}$ and $KC_{\gamma s2}$ both have unusually complex axons that wrap around the surface of the gamma lobe and feature a single dorsal branch; $KC_{\gamma s1}$ innervates all three accessory calyces and also exhibits a striking dendritic elaboration that extends into the PLP (Figure 10), while $KC_{\gamma s2}$ has a large dendritic claw in the lateral accessory calyx (IACA) and smaller dendritic branches in the ventroanterior CA (Marin et al., 2020; Figure 12-figure supplement 2). $KC_{\gamma s3}$ and $KC_{\gamma s4}$ have axon morphologies more similar to those of canonical KC_{γ} neurons, but $KC_{\gamma s3}$ receives input in the dorsal accessory calyx (dACA) and ventral accessory calyx (vACA), and $KC_{\gamma s4}$ receives input in the dACA and anterior CA. (D) $KC_{\gamma d}$ dendrites innervate the vACA and their axons contribute to the dorsal layer of the γ lobe. The 99 $KC_{\gamma d}$ found in sub-clusters 3.3, 3.4, 3.5 and 3.6 are shown in blue; the other γ KCs found in cluster 3 are shown in grey. (D') Space-filling morphologies of the same γd KCs shown in blue, with the MB shown in grey.

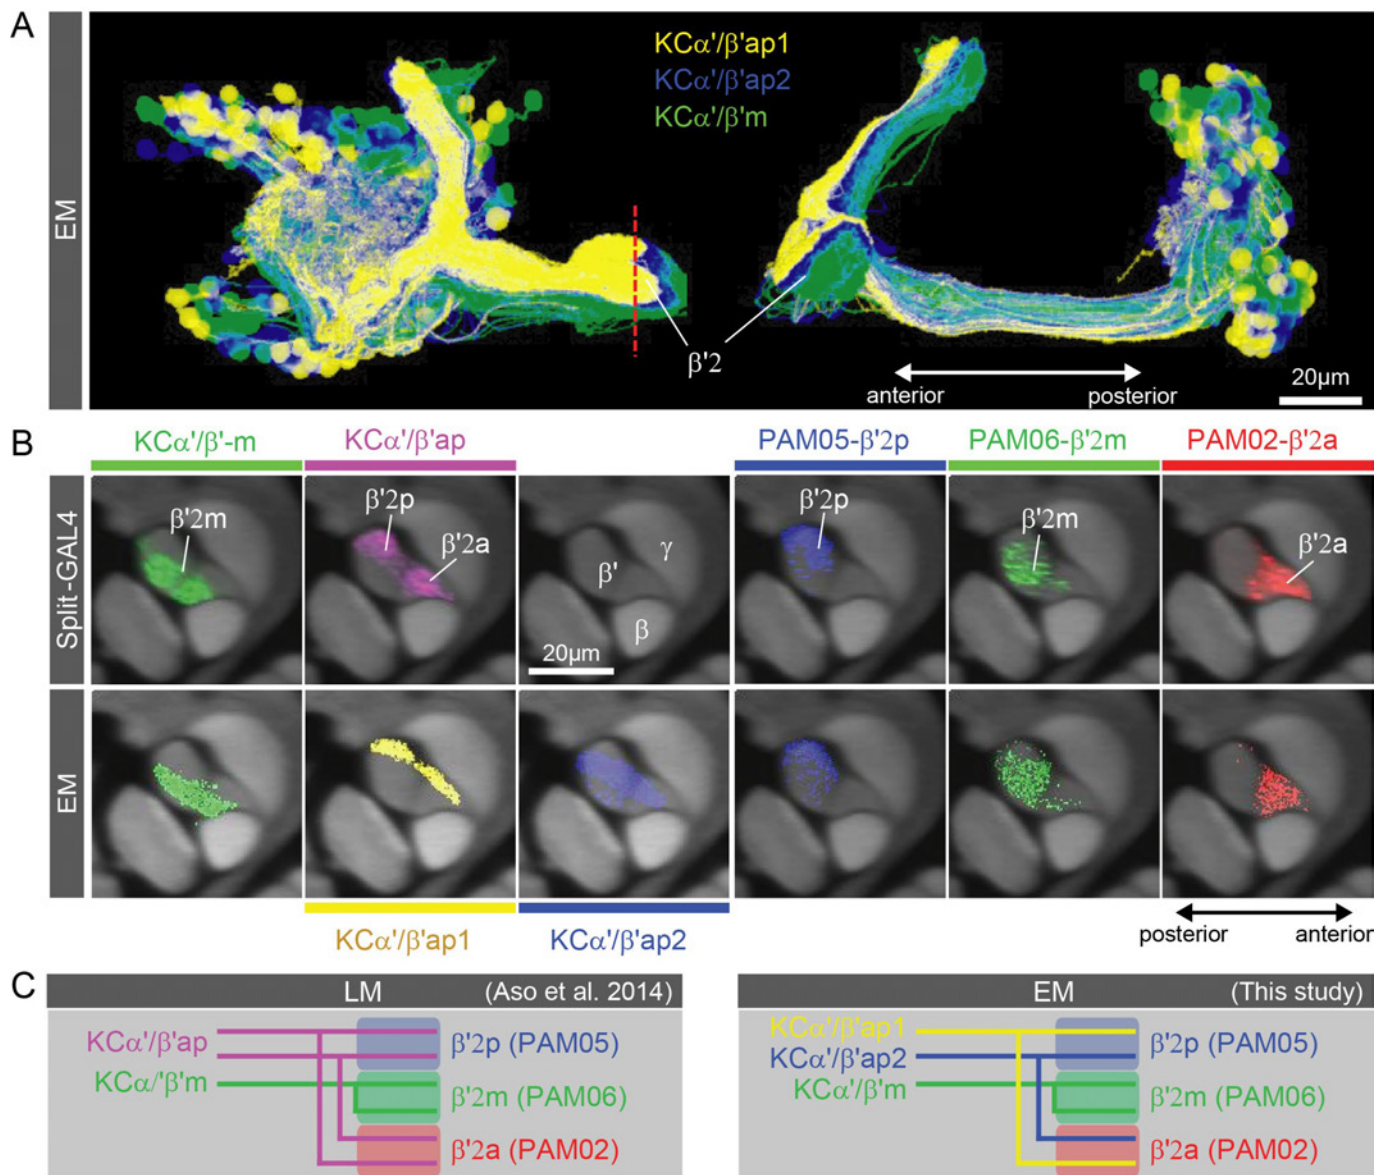

Figure 4-figure supplement 3. Further explanation of KC subtype nomenclature.

(A) Three subtypes of α'/β' KCs in the hemibrain EM data set are shown in the coordinates of the JF2018 standard brain in frontal (left) and sagittal view (right). The red dashed line indicates the position of the cross section of the MB β' lobe shown in (B). (B) Innervation patterns of KCs and PAM DANs in the $\beta'2$ compartment. The reference neuropil stain from the JF2018 standard brain is shown in all panels in grey. Top: Two classes of KCs and three classes of PAM cluster DANs were defined by split-GAL4 drivers (Aso et al., 2014a) and light microscopic images of those split-GAL4 lines are shown: $KC\alpha'/\beta'm$, MB418B; $KC\alpha'/\beta'ap$, MB463B; reference neuropil stain; PAM05- $\beta'2p$, MB056B; PAM06- $\beta'2m$, MB032B; PAM02- $\beta'2a$, MB109B. Bottom: The positions of the indicated KC and PAM cell types are based on the hemibrain EM dataset, after transfer into the JF2018 standard brain coordinate system and color-coded. (C) Comparison of LM and EM data sets. Each $\alpha'/\beta'ap$ bifurcates and innervates both $\beta'2a$ and $\beta'2p$, coincident with the PAM02 and PAM05 innervation patterns, respectively. Morphological clustering revealed three classes of $KC\alpha'/\beta'$, subdividing $\alpha'/\beta'ap$ into two classes: $\alpha'/\beta'ap1$ and $\alpha'/\beta'ap2$. $KC\alpha'/\beta'ap1$, $KC\alpha'/\beta'ap2$ and $KC\alpha'/\beta'm$ likely correspond to $KC\alpha'/\beta'a$, $KC\alpha'/\beta'm$ and $KC\alpha'/\beta'p$, respectively, in Tanaka et al. (2008). However, we followed the nomenclature in Aso et al. (2014a) to minimize confusion with established names based on split-GAL4 driver lines.

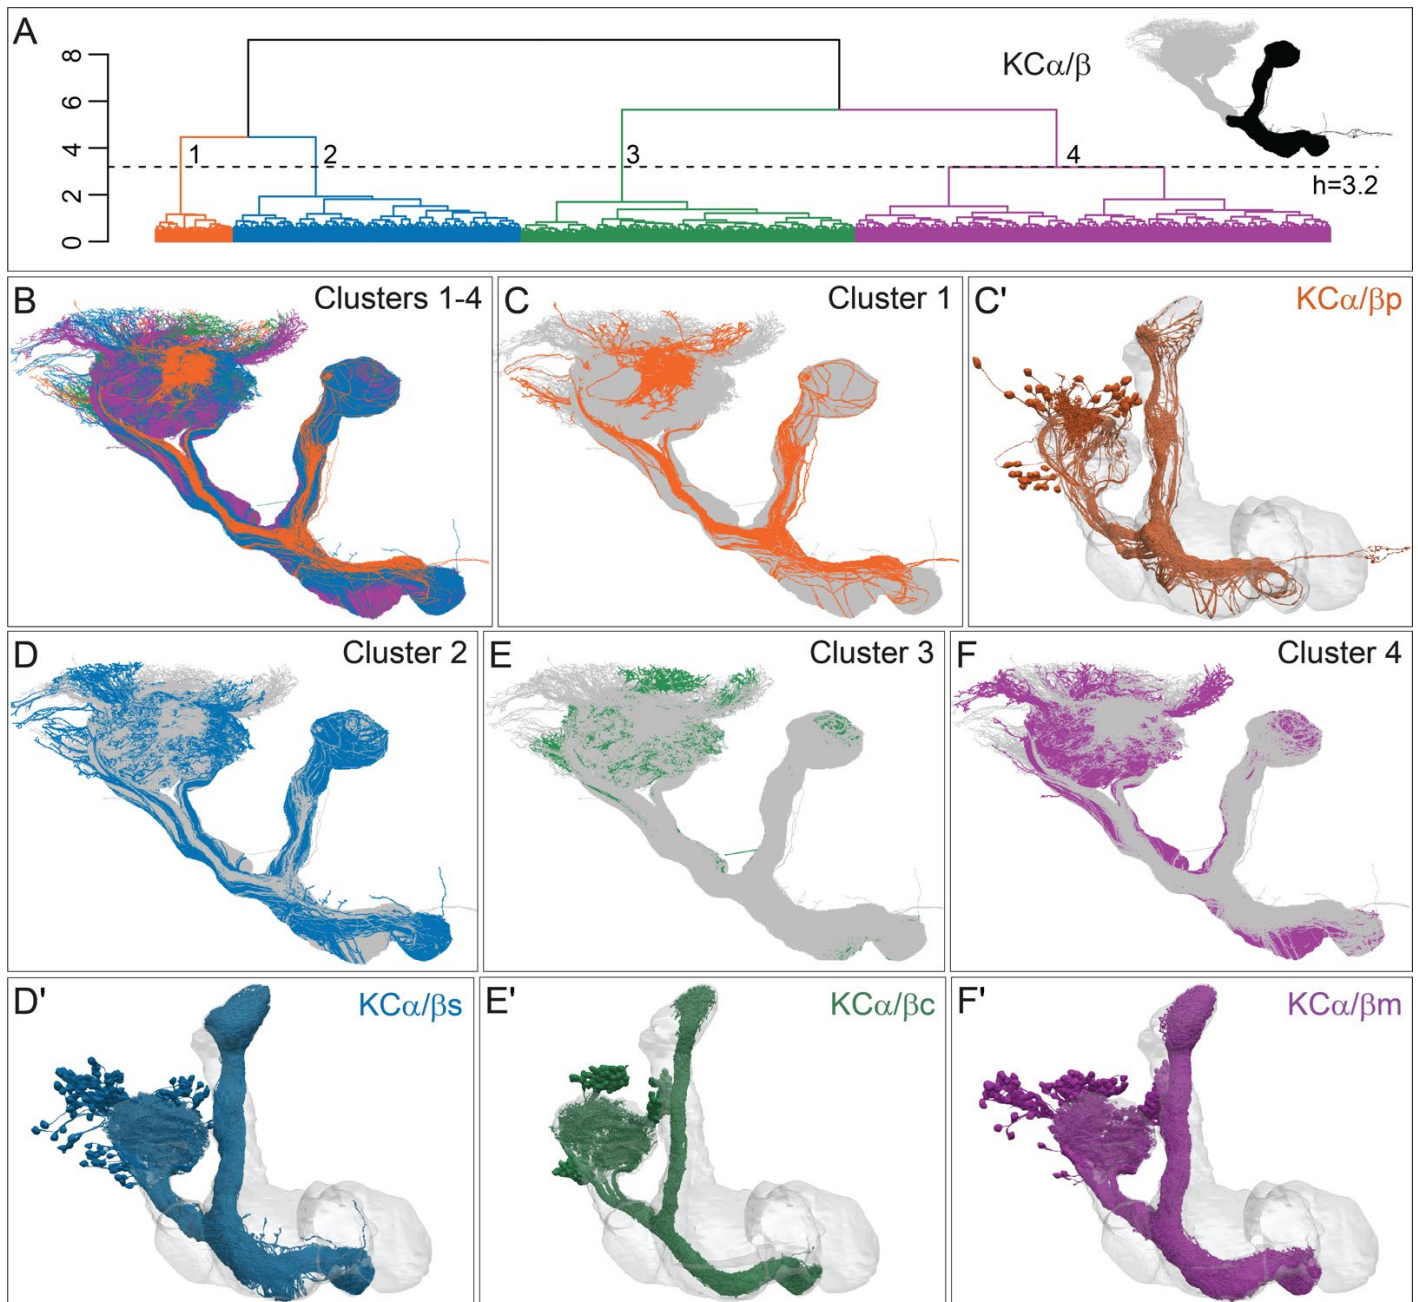

Figure 4-figure supplement 4. Four distinct morphological subtypes of $KC\alpha/\beta$.

(A) Morphological hierarchical clustering based on NBLAST scores for all-by-all comparison of $KC\alpha/\beta$ carried out on that portion of their axons found in the lobes (black area in inset) is shown. When cut at height 3.2 (dashed line), α/β KCs are split into four subtypes. (B) $KC\alpha/\beta$ skeletons shown color-coded to match the clustering in (A). (C) $KC\alpha/\beta p$, cluster 1, shown in rust, with the remaining α/β KCs shown in grey. (C') Space-filling morphologies of the same $KC\alpha/\beta p$ shown in rust, with the MB shown in grey. (D) $KC\alpha/\beta s$ skeletons, cluster 2, shown in blue, with the remaining α/β KCs shown in grey. (D') Space-filling morphologies of the same $KC\alpha/\beta s$ shown in blue, with the MB shown in grey. (E) $KC\alpha/\beta c$ skeletons, cluster 3, shown in green, with the remaining α/β KCs shown in grey. (E') Space-filling morphologies of the same $KC\alpha/\beta c$ shown in green, with the MB shown in grey. (F) $KC\alpha/\beta m$ skeletons, cluster 4, shown in magenta, with the remaining α/β KCs shown in grey. (F') Space-filling morphologies of the same $KC\alpha/\beta m$ shown in magenta, with the MB shown in grey.

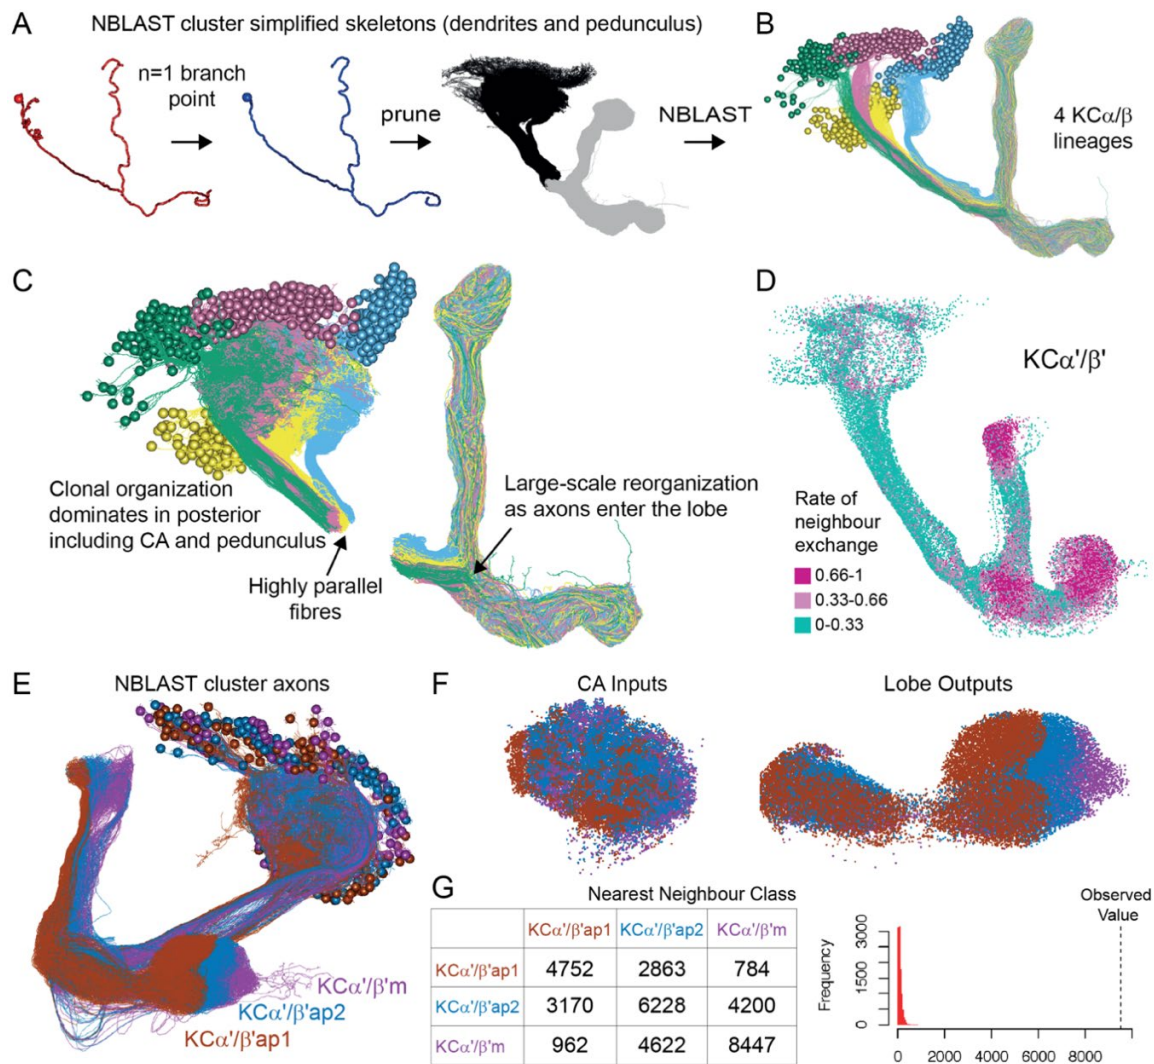

Figure 5. Organizational features of KC projections.

(A) KCs were simplified to skeletons with one major branch point which were used as input for NBLAST all-by-all whole neuron clustering. (B) This clustering revealed the four clonal units that make up the mushroom body (shown here for $KC\alpha/\beta$). (C) Full neuronal morphologies of the four clusters show that the positions of the neurons in the CA are strongly influenced by this fourfold clonal unit structure, which is also reflected in the arrangement of the highly parallel fibers in the pedunculus. On entering the lobes, the axons reorganize, and the neurons from the four clusters become intermingled. (D) Visualization of the rate of change in KC neighbors quantified as the fraction of 10 nearest neighbors that change compared with a position 5 μm closer to the soma. Large values imply a rapid change in the neighbors of individual KC fibers, which is observed at the entry and tips of the $KC\alpha'/\beta'$ lobe as illustrated here. Figure 5-figure supplement 1B shows similar visualizations for the $KC\gamma$ and $KC\alpha/\beta$ lobes; rapid change in neighbors is seen throughout the $KC\gamma$ lobe while $KC\alpha/\beta$ neurons show an intermediate rate of change. (E) NBLAST clustering of the axons of α'/β' KCs reveals three clear laminae in the vertical and horizontal lobes, which correlate with a layered organization in the CA and correspond to the three $KC\alpha'/\beta'$ subtypes. (F) A similar organization is seen for $KC\alpha'/\beta'$ dendrites in the CA and axon outputs in the lobes. (G) As a statistical test for the correlated lobe/CA organization into three subtypes, each synapse in the CA was matched with its closest neighbor from another neuron and the subtype of that neighbor recorded. The contingency table (left) shows that nearest neighbor synapses were most commonly from the same subtype. A permutation test ($n=10000$) confirmed that this statistic was far higher than expected by chance (right).

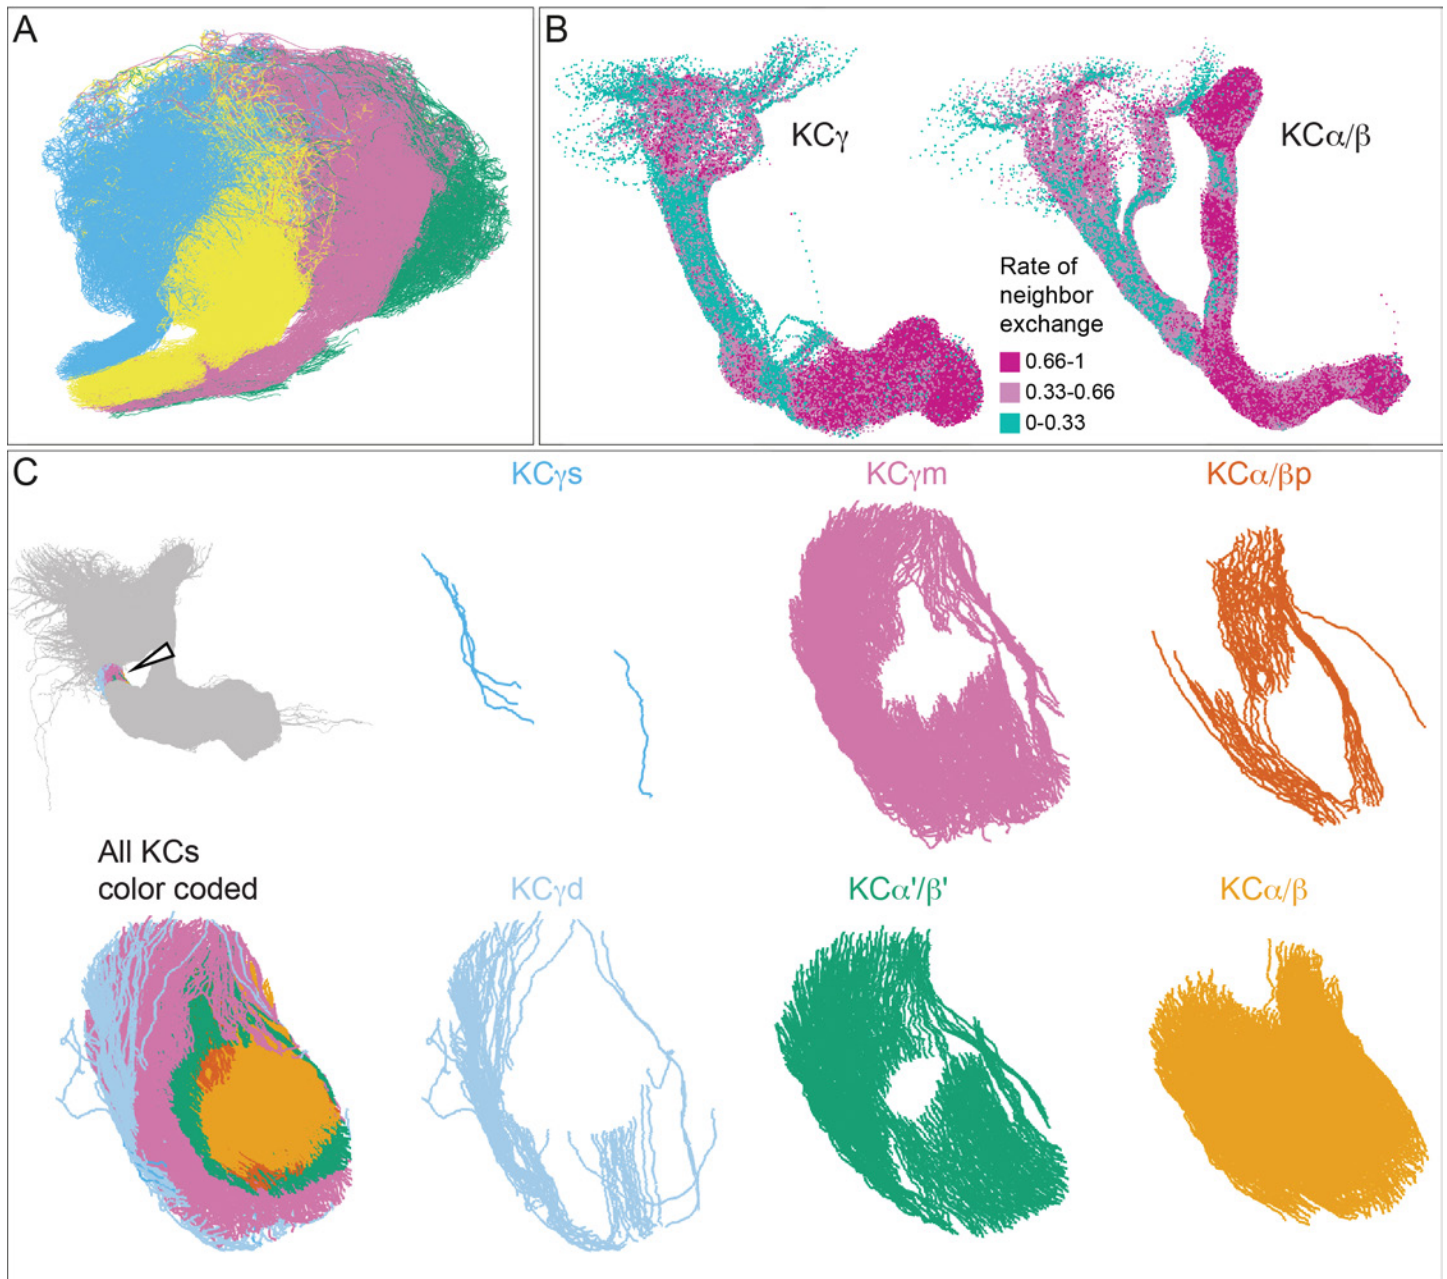

Figure 5-figure supplement 1. Additional organizational features of KC projections.

(A) Posterior view of the CA showing the four clonal units that make up α'/β' KCs (Figure 5B) as revealed by NBLAST clustering (Figure 5A). (B) Visualization of the rate of change in KC neighbors quantified as the fraction of 10 nearest neighbors that change compared with a position $5\mu\text{m}$ closer to the soma. Large values imply a rapid change in the neighbors of individual KC fibers, which are observed all the way along γm KCs in the γ lobe; much lower rates of rearrangement are seen in the pedunculus and in segments of the α/β KCs in the vertical lobe. (C) Cross-sections through the mushroom body pedunculus, at the point indicated by the hollow arrowhead, showing the organization of KC types by birth order, with the first-born types ($\text{KC}_{\gamma\text{ys}}$ and $\text{KC}_{\gamma\text{d}}$) generally more peripheral and the last-born type ($\text{KC}_{\alpha/\beta}$) more central.

cell type	α'/β' ap1	α'/β' ap2	α'/β' m	α/β c	α/β m	α/β s	α/β p	γ d	γ m	γ t	γ s (1-4)

Figure 5-figure supplement 2. KC-to-KC synapses.

The total number of synapses/1000 made between the indicated KC types in the MB (including the lobes, pedunculus and calyces) are shown. Only connections totalling >500 synapses are shown, except for those involving γ t and γ s where connections greater than 50 synapses were included because of the small numbers of cells of these types. The four γ s cell types were pooled. The y-axis shows postsynaptic cell types and the x-axis presynaptic cell types. The number of KCs of each type is shown.

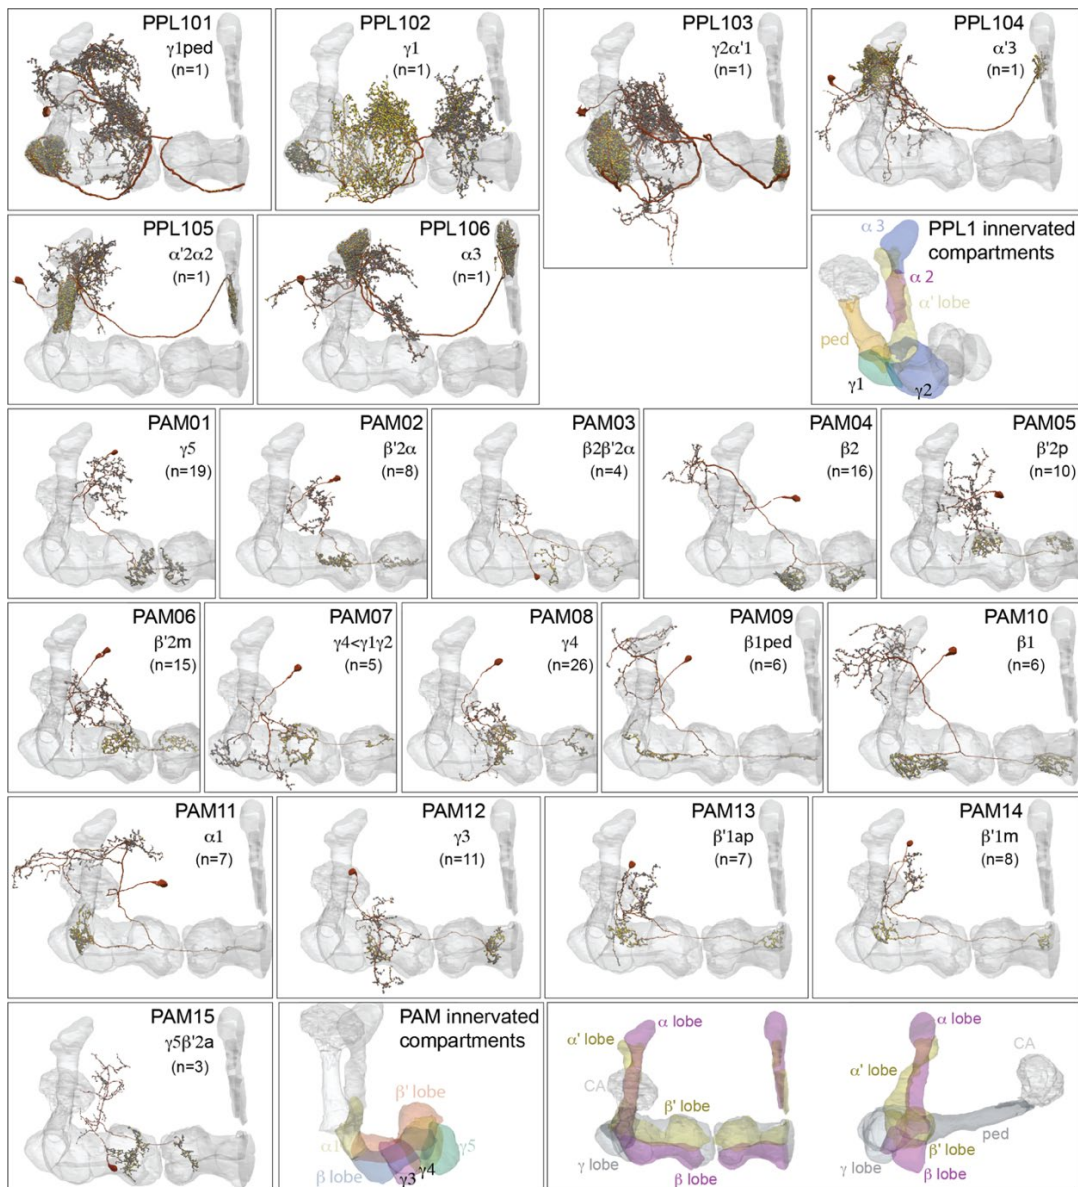

Figure 6. Dopaminergic neurons (DANs).

Each panel shows a DAN cell type, with its name, the compartment(s) it innervates and the number of cells of that type per brain hemisphere indicated; the outline of the MB lobes and CA are shown in grey, in a perspective view from an oblique angle to better display neuronal morphology. Figure 6-figure supplement 1 shows which DANs, MBONs and KCs are found in each compartment. PPL1 dopaminergic neurons are divided into six cell types, [PPL101](#), [PPL102](#), [PPL103](#), [PPL104](#), [PPL105](#), and [PPL106](#). As a population, the PPL1 neurons innervate the α' lobe, α lobe compartments 2 and 3, and γ lobe compartments 1 and 2, as illustrated. There is only one PPL1 DAN of each type per hemisphere, but they send their axons bilaterally to innervate the same MB compartments, although less densely, in the other brain hemisphere (see Aso et al. 2014a). All other compartments are innervated by PAM DANs, as illustrated: [PAM01](#), [PAM02](#), [PAM03](#), [PAM04](#), [PAM05](#), [PAM06](#), [PAM07](#), [PAM08](#), [PAM09](#), [PAM10](#), [PAM11](#), [PAM12](#), [PAM13](#), [PAM14](#), and [PAM15](#). Unlike the PPL1 DANs, multiple PAM DANs of the same cell type innervate the same compartment, and in some cases the same compartment has different PAM DAN types innervating different subdomains of the compartment. MB lobes are shown in grey. A single representative neuron is shown for each cell type in magenta, with grey dots indicating postsynaptic sites and yellow dots indicating presynaptic sites. Images showing the identity of the MB lobes are shown in the lower right.

● Glu ● GABA ● ACh ● N.D.

Figure 6-figure supplement 1. Table of cell types found in each MB compartment.

This table shows which KCs, DANs and MBONs are found in each of the 15 compartments of the MB lobes. Both the short names used throughout this paper and the longer names used in Aso et al. (2014a) are shown. MBONs or DANs that innervate more than one compartment are marked with an asterisk. MBON names are color-coded based on neurotransmitter as indicated.

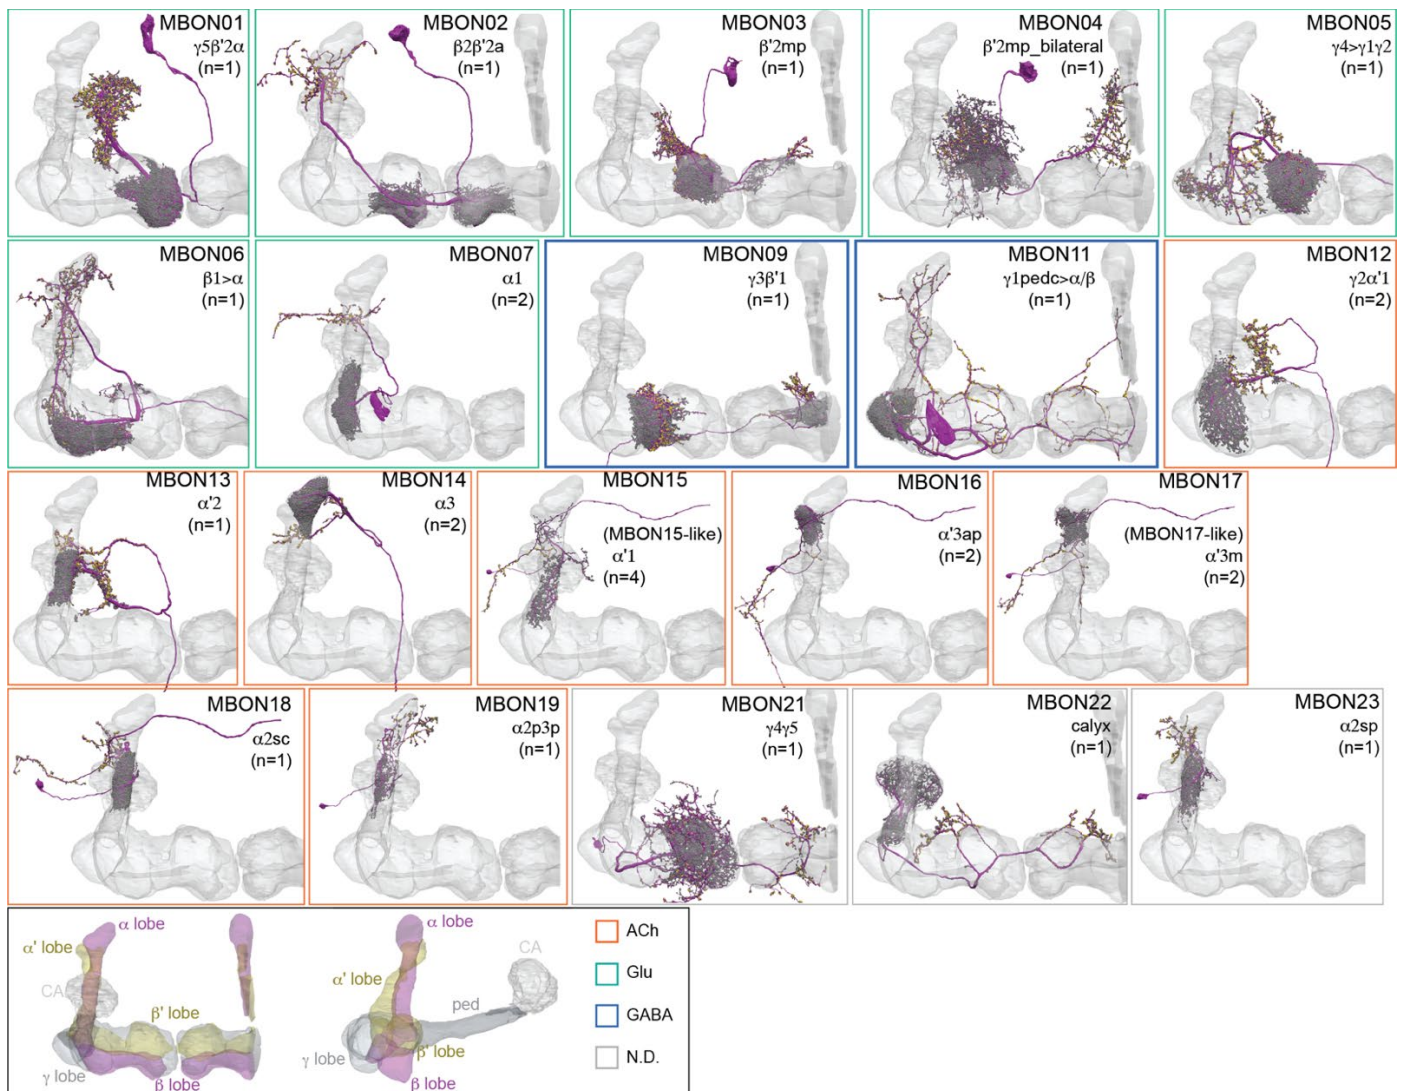

Figure 7. Mushroom Body Output Neurons (MBONs).

Each panel shows one of the previously described 20 types of MBONs, with its name, the compartment(s) it innervates and the number of cells of that type per brain hemisphere indicated (Aso et al., 2014a; Takemura et al., 2017); the outline of the MB lobes and CA are shown in grey, in a perspective view from an oblique angle to better display neuronal morphology. MB lobes are shown in grey. A single representative neuron is shown for each cell type (magenta), with grey and yellow dots indicating pre synaptic and presynaptic sites respectively. The bounding box for each neuron is color coded by the neurotransmitter used by that MBON; color key shown in the last panel. These MBONs are considered to be typical in that their dendritic arbors are confined to the MB lobes. We reclassified MBON10 and MBON20 (Aso et al., 2014a) as atypical MBONs since their dendrites extend outside the MB lobes. MBON08, defined by split-GAL4 line MB083C (Aso et al., 2014a), was not found in the hemibrain volume. For the other 21 MBON types, we found only minor differences with previous studies (Aso et al., 2014a; Takemura et al., 2017). For example, MBON15 ($\alpha'1$) and MBON17 ($\alpha'3m$), which each were described as having two cells in (Aso et al., 2014a; Takemura et al., 2017), had additional cells in the hemibrain that were similar in morphology, but had some connectivity differences, that we refer to as MBON15-like and MBON17-like. However, since our observations are based on a single individual, we did not split them into separate cell types. Links to the neuPrint records of these MBON types are as follows: [MBON01](#), [MBON02](#), [MBON03](#), [MBON04](#), [MBON05](#), [MBON06](#), [MBON07](#), [MBON09](#), [MBON11](#), [MBON12](#), [MBON13](#), [MBON14](#), [MBON15 \(including MBON15-like\)](#), [MBON16](#), [MBON17 \(including MBON17-like\)](#), [MBON18](#), [MBON19](#), [MBON20](#), [MBON21](#), [MBON22](#), and [MBON23](#).

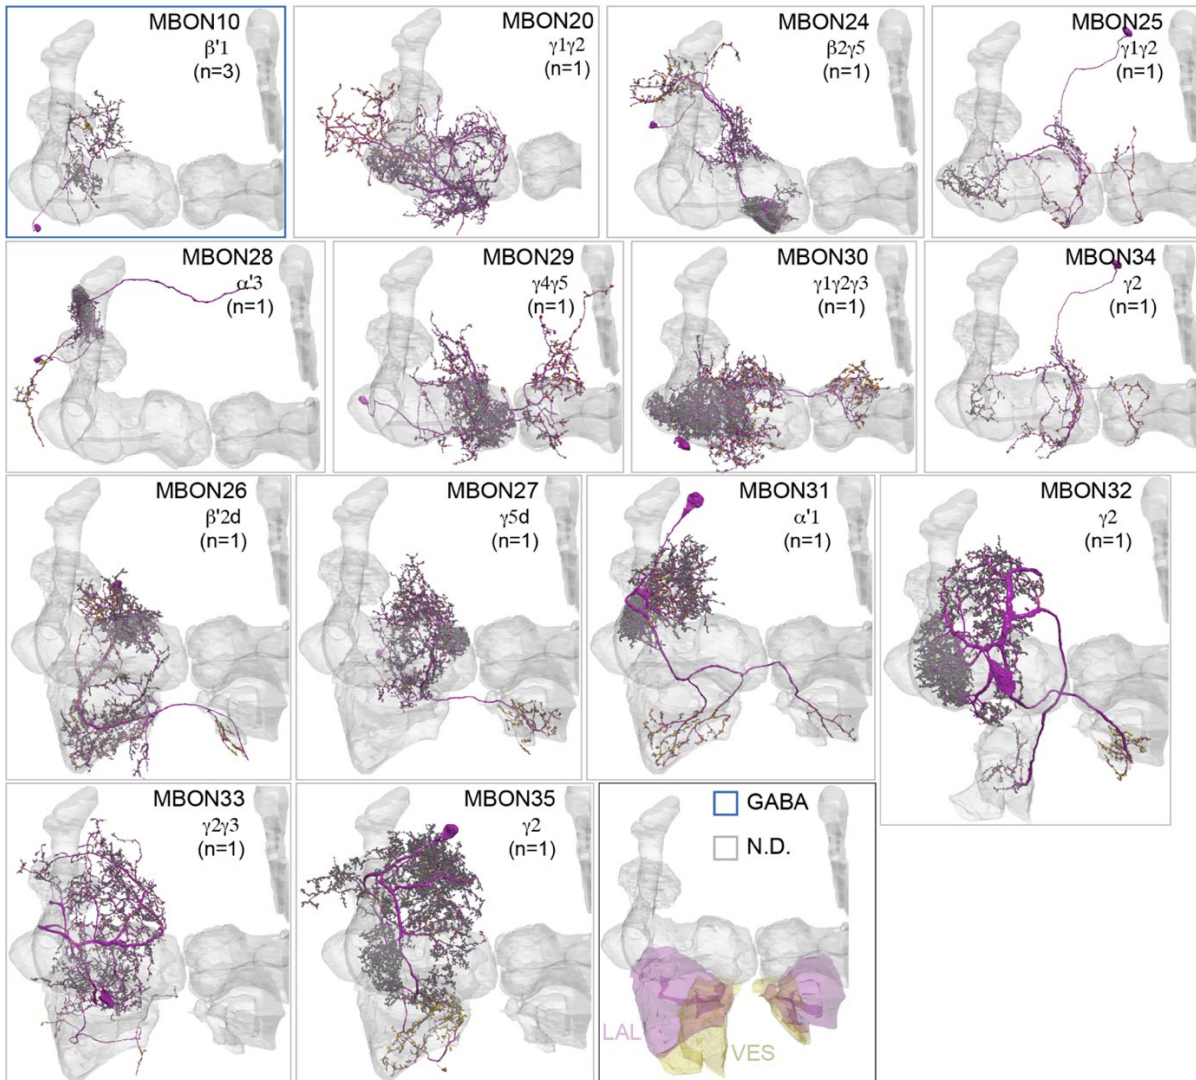

Figure 8. Atypical MBONs.

Each panel shows one of the 14 types of atypical MBONs, with its name, the compartment(s) it innervates and the number of cells of that type per brain hemisphere indicated. Figure 6-figure supplement 1 shows which DANs, MBONs and KCs are found in each compartment. MB lobes are shown in grey and in the bottom right panel the lateral accessory lobe (LAL) and vest (VES) brain areas are highlighted. Neuronal morphologies are shown with dark grey dots indicating postsynaptic sites and yellow dots indicating presynaptic sites. The MBONs shown in this figure are considered to be atypical in that their dendritic arbors are only partially within the MB lobes. Twelve of these types were discovered in the course of the current study. The other two, the GABAergic MBON10 and MBON20, were described by Aso et al. (2014a), but we have reclassified them here as atypical MBONs because they have dendrites both inside and outside the MB lobes. The three MBON10s in the EM volume have 69%, 68% and 50% of their postsynaptic sites outside the MB lobes; one is shown here. All the other atypical MBONs occur once per hemisphere. Unlike most typical MBONs that innervate brain areas that are dorsal to the MB, six of the atypical MBONs innervate areas that are ventral to the MB. The LAL is a target of several atypical MBONs, and one also innervates the VES. More detailed information about each of the atypical MBONs can be found in Figure 8-figure supplements 1-14 and Videos 7-20. Figure 8-figure supplement 15 compares the non-MB inputs to these MBONs. Neurotransmitters of atypical MBONs are unknown except MBON10, as indicated by the color of the bounding box. Links to the neuPrint records of these MBON types are as follows: [MBON10](#), [MBON24](#), [MBON25](#), [MBON26](#), [MBON27](#), [MBON28](#), [MBON29](#), [MBON30](#), [MBON31](#), [MBON32](#), [MBON33](#), [MBON34](#), and [MBON35](#).

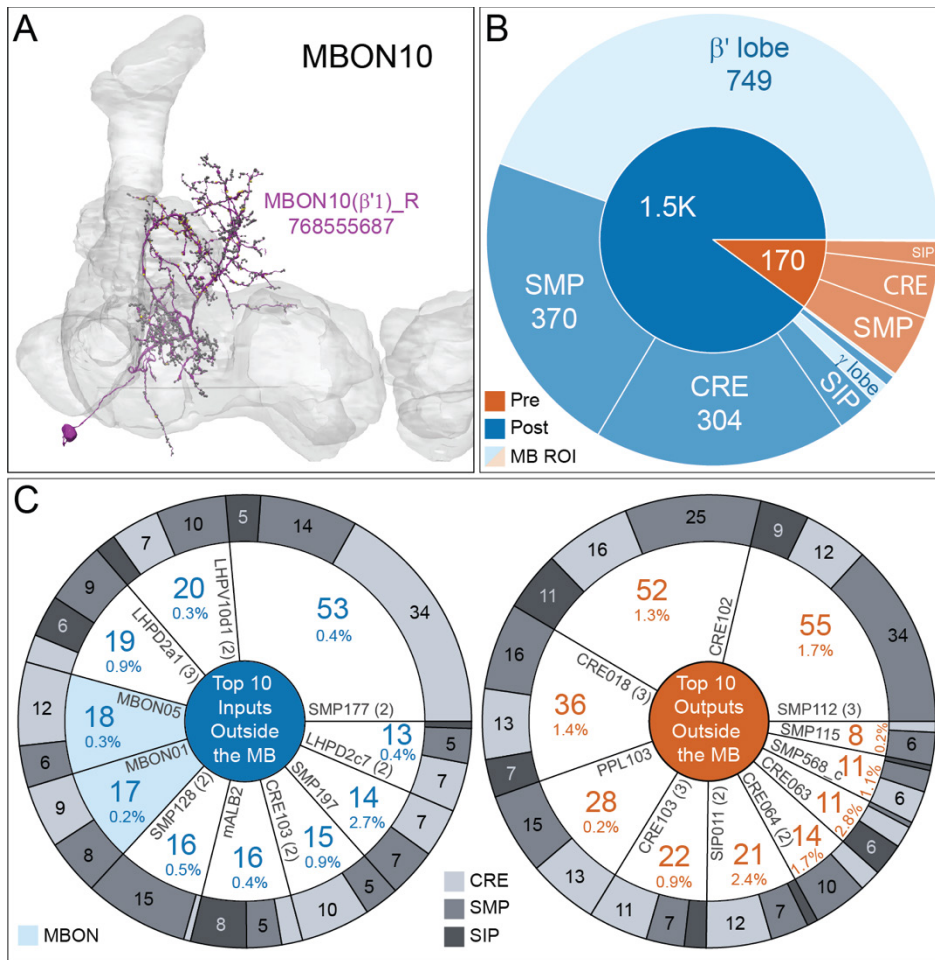

Figure 8-figure supplement 1. Atypical MBON10.

(A) Atypical MBON10 is the only atypical MBON cell type with more than one cell per brain hemisphere. One of the three MBON10s is shown here; all three cells are shown in Video 7. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. (B) A pie chart showing the distribution of MBON10's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON10's pre- and postsynaptic sites; the numbers represent the MBON10 shown in A. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON10's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [SMP177](#), [LHPV10d1](#), [LHPD2a1](#), [MBON05](#), [MBON01](#), [mALB2](#), [SMP128](#), [CRE103](#), [SMP197](#), and [LHPD2c7](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON10; the shading of the outer ring of the pie chart indicates where these synapses are located. Note that two typical MBONs synapse onto MBON10, MBON01 (γ 5 β' 2a) and MBON05 (γ 4 γ 1 γ 2). MBON10's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [SMP112](#), [CRE102](#), [CRE018](#), [PPL103](#), [CRE103](#), [SIP011](#), [CRE064](#), [SMP568_c](#), [CRE063](#), and [SMP115](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neurons input that is provided by MBON10; the shading of the outer ring of the pie chart indicates where these synapses are located.

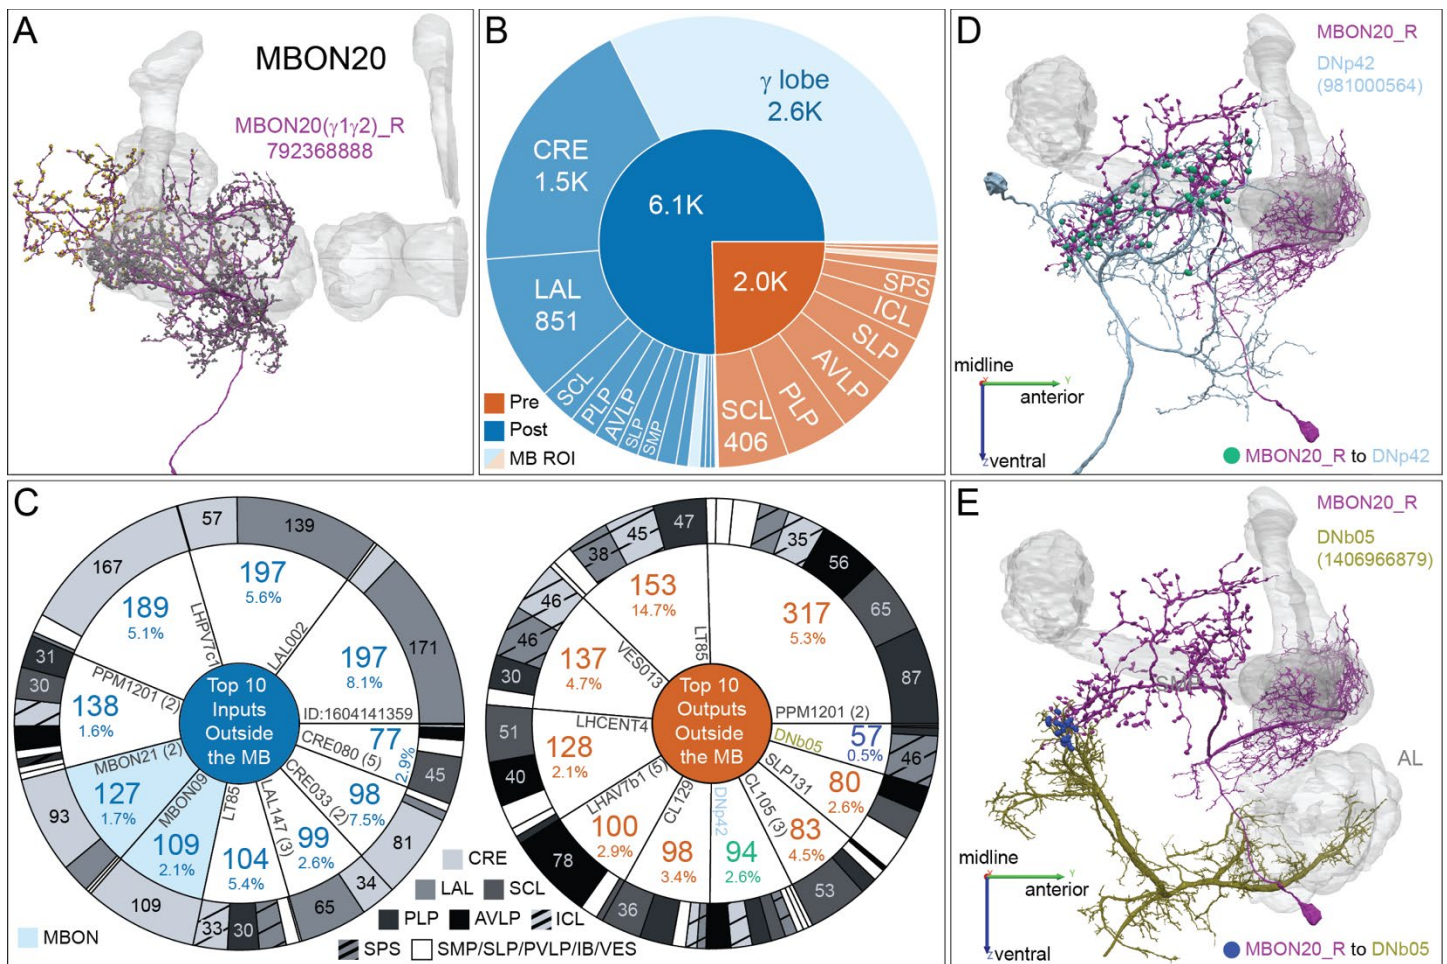

Figure 8-figure supplement 2. MBON20.

(A) Atypical MBON20 ($\gamma 1\gamma 2$) is shown here and in Video 8. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON20 receives 45 percent of its input from sites within MB lobes and 85 percent of those input are in the $\gamma 1\gamma 2$ compartments. (B) A pie chart showing the distribution of MBON20's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON20's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON20's top ten inputs by neuron type outside the MBON lobes are shown; links to these cell types in neuPrint are: [1604141359](#), [LAL002](#), [LHPV7c1](#), [PPM1201](#), MBON21, MBON09, [LT85](#), [LAL147](#), [CRE033](#), and [CRE080](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON20; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON20's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [PPM1201](#), [LT85](#), [VES013](#), [LHCENT4](#), [LHAV7b1](#), [CL129](#), [DNp42](#), [CL105](#), [SLP131](#), and [DNb05](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON20; the shading of the outer ring of the pie chart indicates where these synapses are located. Synapse numbers in highlighted text indicate neurons further discussed in panel D and E and are color-coded to match the neurons in these panels. Note MBON20 makes strong reciprocal connections with LT85, which is a LO tangential neuron conveying visual information, and PPM1201. (D-E) Although not all DNs have been identified, there are at least two individual DNs that are strongly connected to MBON20. (D) DNp42, connects to MBON20 with 94 synapses in dorsal brain regions, including SCL and PLP. (E) DNb05, connects to MBON20 with 57 synapses in SPS. Note DNb05 also receives input from PNs in the AL.

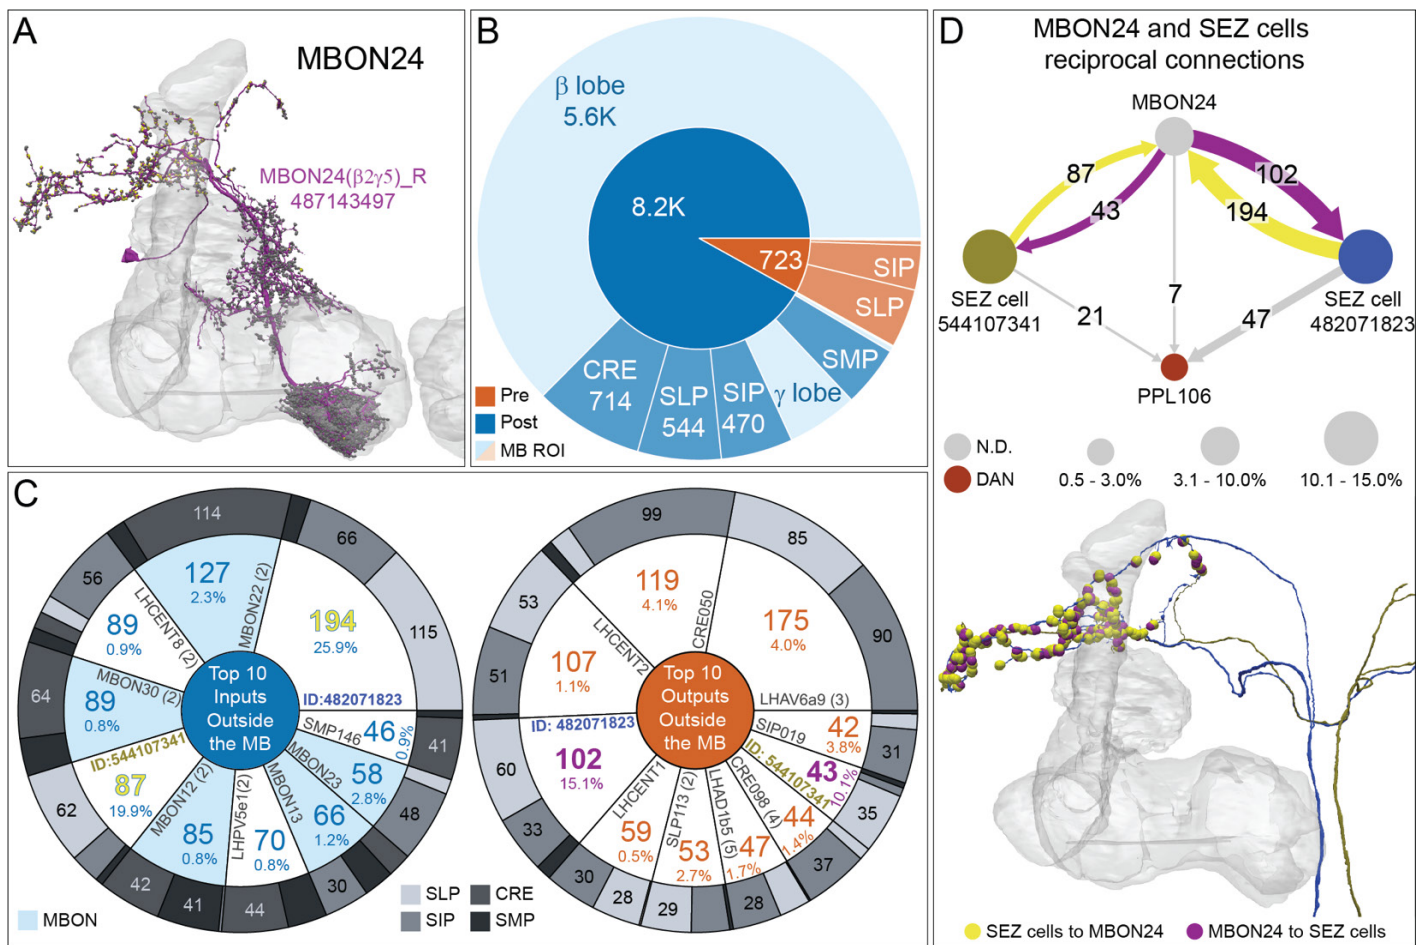

Figure 8-figure supplement 3. MBON24.

(A) Atypical MBON24 ($\beta_2\gamma_5$) is shown here and in Video 9. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON24 receives 75 percent of its inputs from sites within the MB lobes and 90 percent of these inputs are in the β_2 compartment. (B) A pie chart showing the distribution of MBON24's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON24's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON24's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [482071823](#), [MBON22](#), [LHCENT8](#), [MBON30](#), [544107341](#), [MBON12](#), [LHPV5e1](#), [MBON13](#), [MBON23](#), and [SMP146](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON24; the shading of the outer ring of the pie chart indicates where these synapses are located. Note that four of MBON24's top input neurons are typical MBONs (indicated in light blue). MBON24's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [LHAV6a9](#), [CRE050](#), [LHCENT2](#), [482071823](#), [LHCENT1](#), [SLP113](#), [LHAD1b5](#), [CRE098](#), [544107341](#), and [SIP019](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neurons input that is provided by MBON24; the shading of the outer ring of the pie chart indicates where these synapses are located. Synapse numbers in highlighted text indicate neurons further discussed in panel D and are color-coded to match the diagrams in panel D. (D) Two of the top inputs to MBON24, and MBON24's reciprocal connections back to them, are shown. These cells send processes outside of the hemibrain volume, presumably to the subesophageal zone (SEZ), as has been confirmed for the more strongly connected of the two (482071823) by reconstructing its counterpart in the FAFB volume (Figure 35 C and E). The same two neurons also provide strong input to a PPL106, contributing more than 0.5% of its total input, and are part of cluster 27 of DAN inputs shown in Figure 31. These SEZ cells also receive strong input from MBON14 (387 synapses).

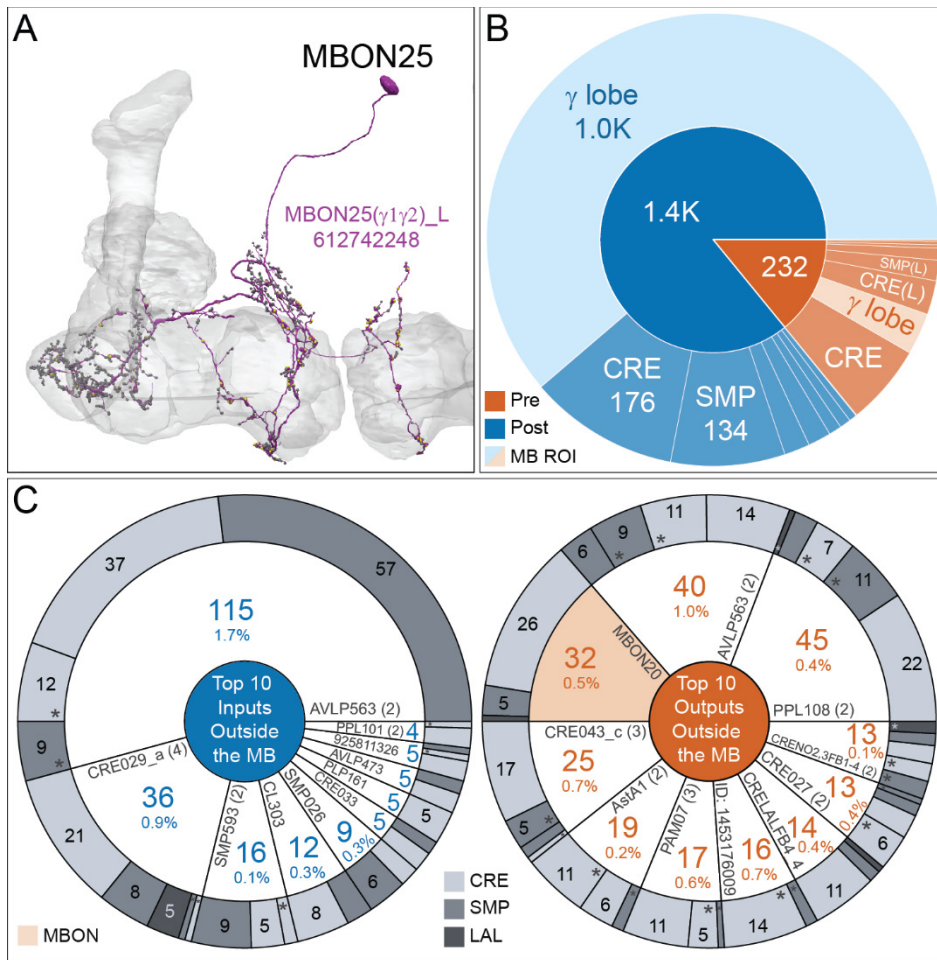

Figure 8-figure supplement 4. Atypical MBON25.

(A) Atypical MBON25 (γ 1 γ 2) is shown here and in Video 10. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON25 receives input in the γ 1 and γ 2 compartments. (B) A pie chart showing the distribution of MBON25's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON25's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. The CRE is MBON25's major output area and MBON25 extends bilaterally to the left hemisphere CRE. (C) MBON25's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [AVLP563](#), [CRE029_a](#), [SMP593](#), [CL303](#), [SMP026](#), [AVLP473](#), [CRE033](#), [PLP161](#), [925811326](#), [PPL102](#), and [PPL101](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON25; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON25's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [PPL108](#), [AVLP563](#), [MBON20](#), [CRE043_c](#), [Asta1](#), [PAM07](#), [1453176009](#), [CRELALFB4_4 \(FB4H\)](#), [CRE027](#), and [CRENO2.3FB1-4 \(FB1H\)](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON25; the shading of the outer ring of the pie chart indicates where these synapses are located (asterisks indicate that these synapses are located in the left hemisphere). MBON25 makes axo-axonal connections outside the MB onto MBON20 (light orange shading); MBON20 and MBON25 both innervate the γ 1 and γ 2 compartments.

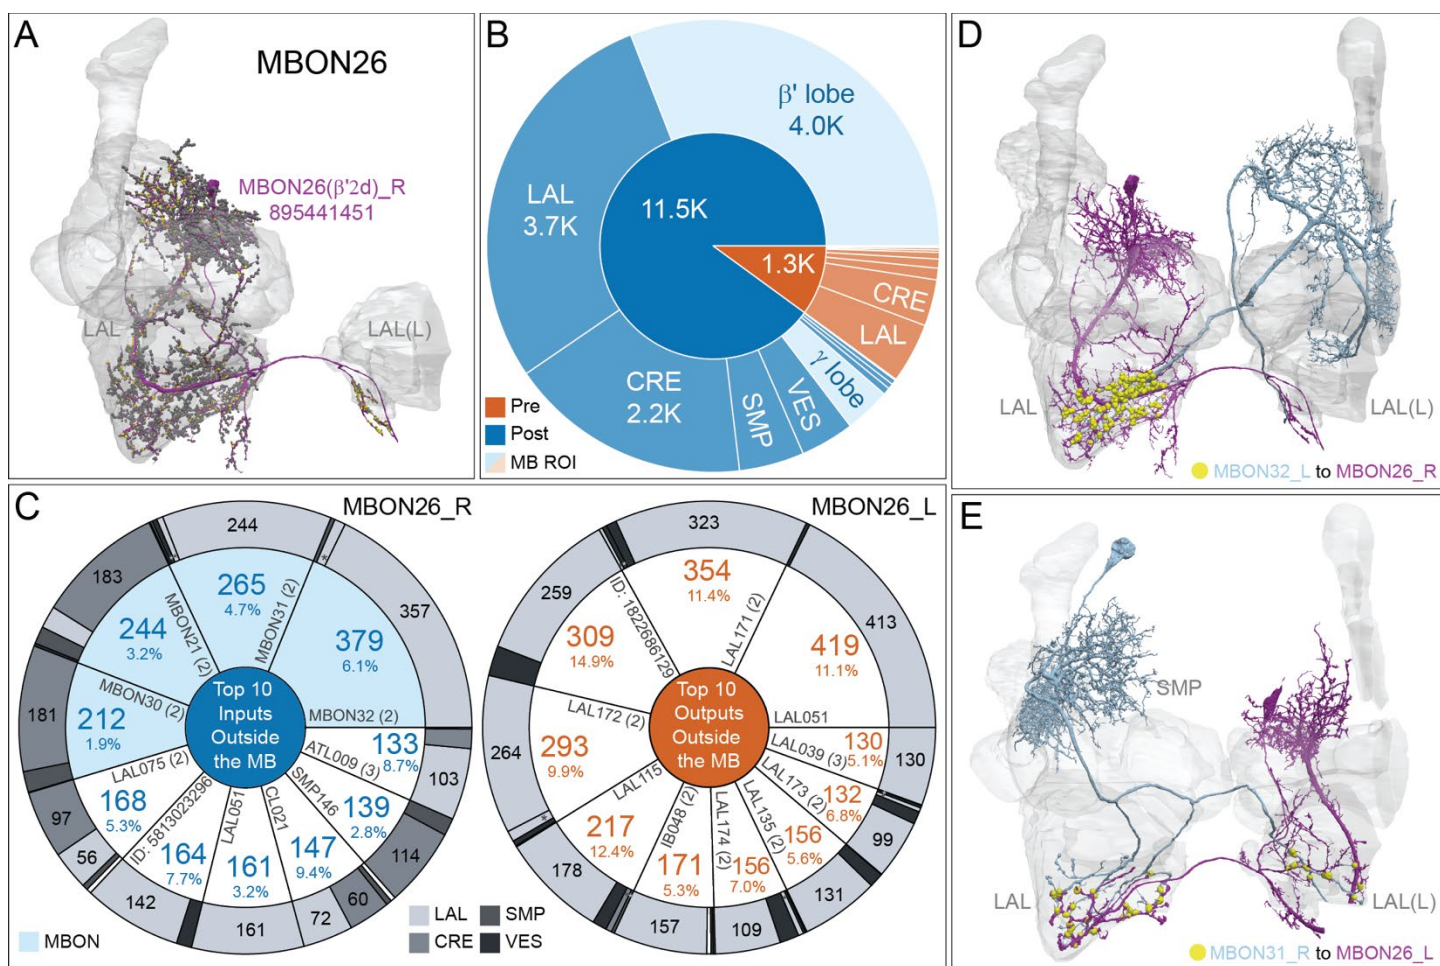

Figure 8-figure supplement 5. Atypical MBON26.

(A) Atypical MBON26 (β' 2d) is shown here and in Video 11. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON26 receives input from the β' 2 compartment. (B) A pie chart showing the distribution of MBON26's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON26's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. Note MBON26_R's output in LAL(L) is incomplete due to the left LAL(L) being only partially contained within the hemibrain volume (see panel D); we therefore display the output of MBON26_L in LAL(R) in the output pie chart to indicate what we believe to be MBON26's full output in the LAL. (C) MBON26's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [MBON32](#), [MBON31](#), [MBON21](#), [MBON30](#), [LAL075](#), [5813023296](#), [LAL051](#), [CL021](#), [SMP146](#), and [ATL009](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON26; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON26's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [LAL051](#), [LAL171](#), [1822686129](#), [LAL172](#), [LAL115](#), [IB048](#), [LAL174](#), [LAL135](#), [LAL173](#), and [LAL039](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON26; the shading of the outer ring of the pie chart indicates where these synapses are located (asterisk indicates that these synapses are located in the left hemisphere). Note that MBON26's strongest inputs come from MBON21 (γ 4 γ 5) and three atypical MBONs, MBON30 (γ 1 γ 2 γ 3), MBON31 (α' 1) and MBON32 (γ 2), (indicated in light blue). MBON26 is at the top layer of an MBON feedforward hierarchy network and also gets strong input from MBON27 (γ 5d) and MBON29 (γ 4 γ 5) (Figure 24; Figure 24-figure supplement 1). (D,E) The connections from MBON31 and MBON32 to MBON 26 occur almost exclusively in the LAL.

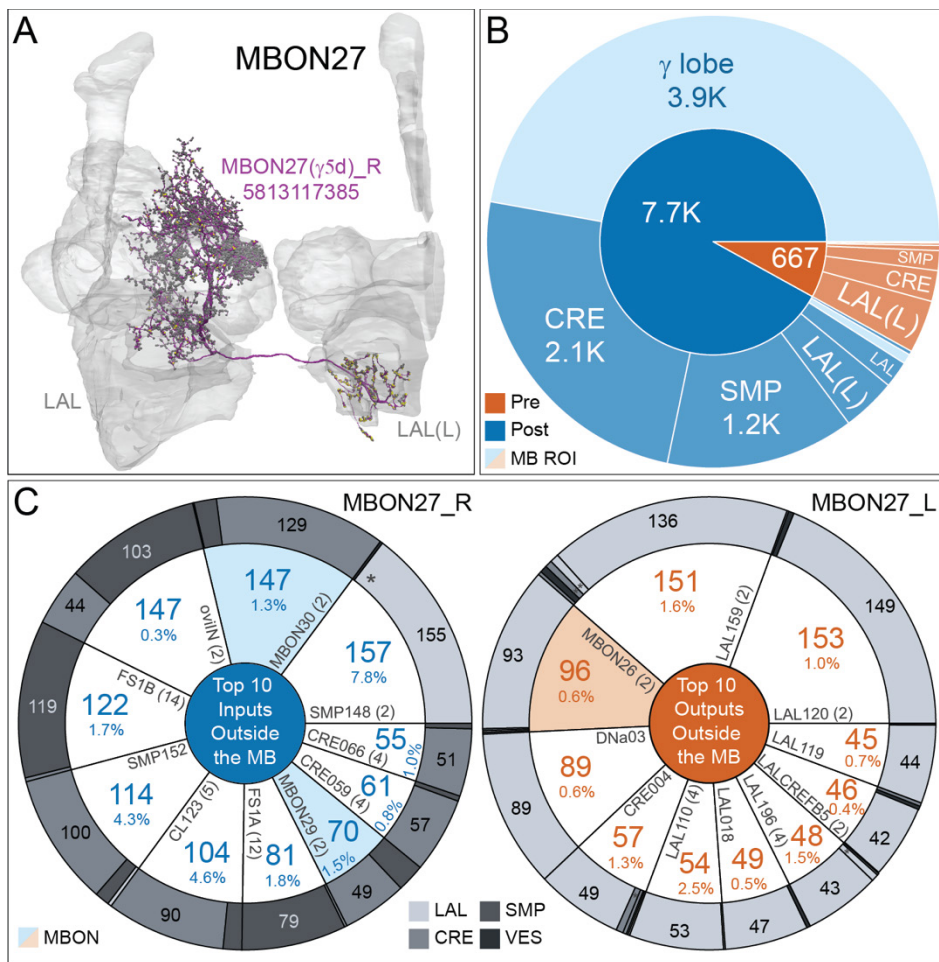

Figure 8-figure supplement 6. Atypical MBON27.

(A) Atypical MBON27 (γ 5d) is shown here and in Video 12. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON27 receives about half its input inside the MB, from the γ 5 compartment, and outputs to both the ipsi- and contralateral LALs. (B) A pie chart showing the distribution of MBON27's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON27's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. The LAL is MBON27's major output area. (C) MBON27's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [SMP148](#), [MBON30](#), [oviIN](#), [FS1B](#), [SMP152](#), [CL123](#), [FS1A](#), [MBON29](#), [CRE059](#), and [CRE066](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON27; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON27's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [LAL120](#), [LAL159](#), [MBON26](#), [DNa03](#), [CRE004](#), [LAL110](#), [LAL018](#), [LAL196](#), [LALCREFB5 \(FB5A\)](#), and [LAL119](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON27; the shading of the outer ring of the pie chart indicates where these synapses are located (asterisk indicates that these synapses are located in the left hemisphere). Note that MBON27 receives input from two atypical MBONs, MBON29 (γ 4 γ 5) and MBON30 (γ 1 γ 2 γ 3), and outputs onto another atypical MBON, MBON26 (β '2d; indicated by the light blue and light orange shading in input and output pie charts respectively).

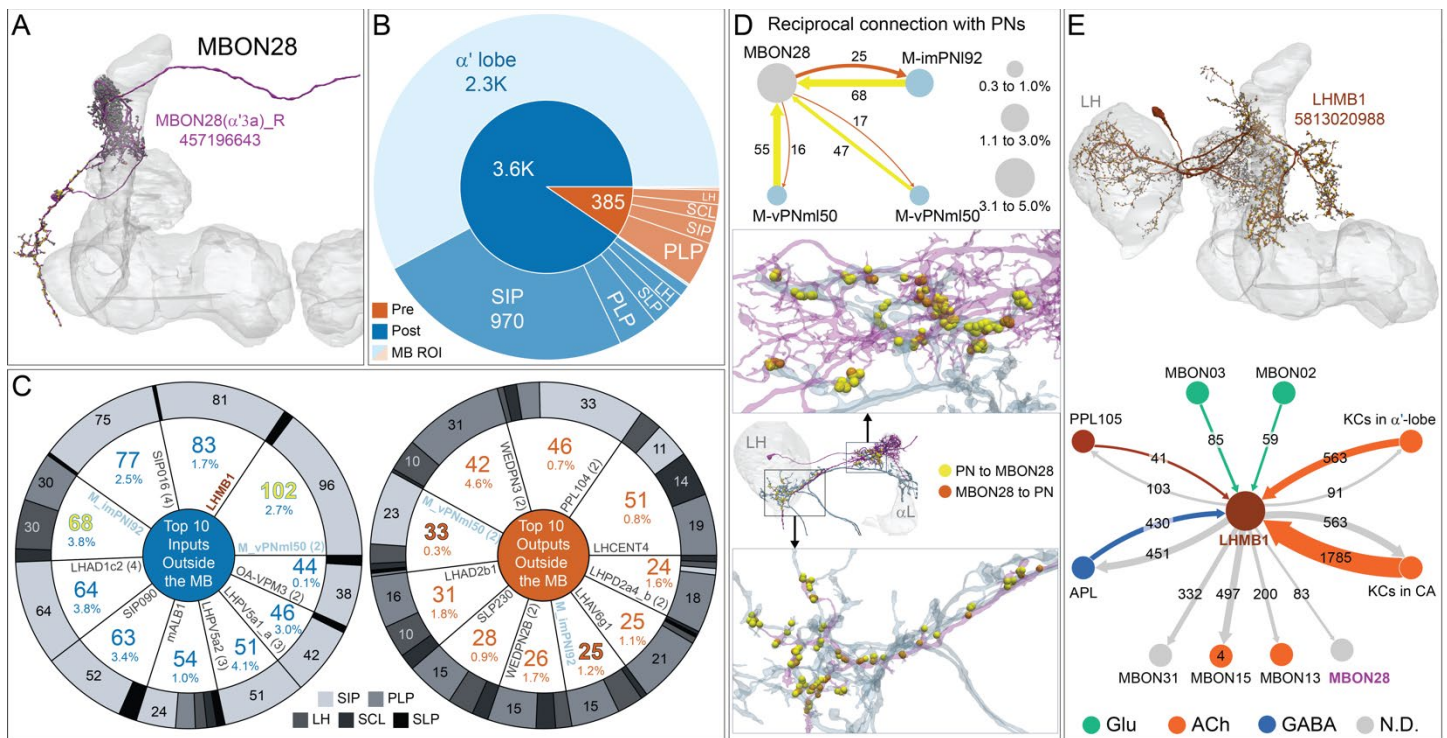

Figure 8-figure supplement 7. Atypical MBON28.

(A) Atypical MBON28 ($\alpha'3$) is shown here and in Video 13. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON 28 receives about 60 percent of its input from the $\alpha'3$ compartment within the MB lobes; within the $\alpha'3$ compartment its arbors have a similar morphology to those of MBON16, but MBON28's dendrites also extend outside the MB lobe. (B) A pie chart showing the distribution of MBON28's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON28's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. The PLP is MBON28's major output area but it also sends output to the LH. (C) MBON28's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [M_vPNml50](#), [LHMB1](#), [SIP016](#), [M_imPN192](#), [LHAD1c2](#), [SIP090](#), [mALB1](#), [LHPV5a2](#), [LHPV5a1_a](#), and [OA-VPM3](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON28; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON28's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [LHCENT4](#), [PPL104](#), [WEDPN3](#), [M_vPNml50](#), [LHAD2b1](#), [SLP230](#), [WEDPN2B](#), [M_imPN192](#), [LHAV6g1](#), and [LHPD2a4_b](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neurons input that is provided by MBON28; the shading of the outer ring of the pie chart indicates where these synapses are located. Synapse numbers in highlighted text indicate neurons further discussed in panel D and are color-coded to match the diagrams in panel D. (D) MBON28 makes strong reciprocal connections with three inhibitory multi-glomerular PNs. The size of the circle representing the PN indicates the percentage of that PN's output that goes to MBON28. The size of the MBON28 circle represents the percentage of its inputs outside the MB provided by the three PNs. This is the only MBON that receives PN input among its top ten inputs. These reciprocal connections are distributed in two major areas: one near the MB, the other near or inside the LH. (E) Left: MBON28's second strongest input neuron, LHMB1, is shown here and in Video 13; LHMB1 innervates both the LH, the CA and the α lobe. Right: Connectivity diagram showing LHMB1's main outputs and inputs. LHMB1 makes synapses onto MBONs on their dendrites inside the lobes as well as outside the MB through axo-axonal connections, and receives input from MBON02 ($\beta2\beta'2a$) and MBON03 ($\beta'2mp$), and reciprocally connects to APL and KCs in both the α lobe and CA.

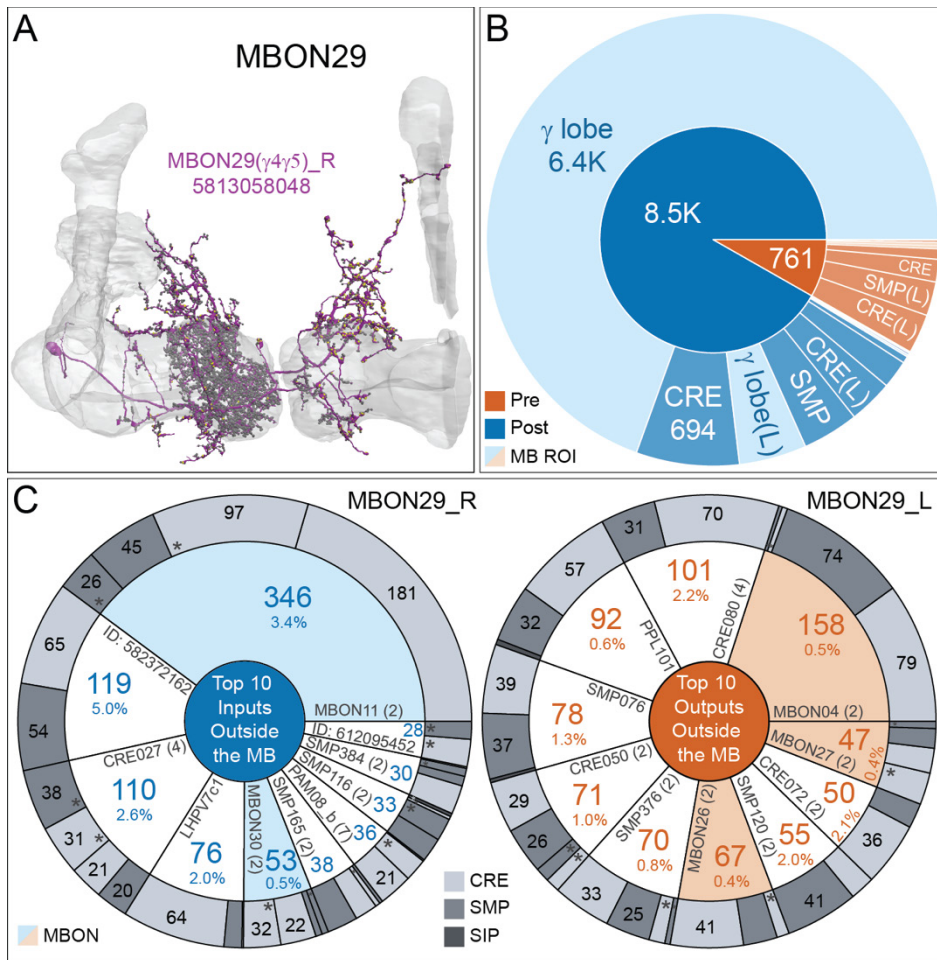

Figure 8-figure supplement 8. Atypical MBON29.

(A) Atypical MBON29 ($\gamma 4\gamma 5$) is shown here and in Video 14. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON29 receives about 80% of its input from the $\gamma 4$ and $\gamma 5$ compartments within the MB lobes. (B) A pie chart showing the distribution of MBON29's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON29's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON29's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [MBON11](#), [582372162](#), [CRE027](#), [LHPV7c1](#), [MBON30](#), [SMP165](#), [PAM08_b](#), [SMP116](#), [SMP384](#), and [612095452](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON29; the shading of the outer ring of the pie chart indicates where these synapses are located (asterisks indicate that these synapses are located in the left hemisphere). MBON29 receives very strong input from MBON11 ($\gamma 1pedc>\alpha/\beta$)_right and _left, which together contribute 9% of MBON29's total input outside MB and also receives input from MBON30 ($\gamma 1\gamma 2\gamma 3$; indicated by the light blue shading in the input pie chart). MBON29 makes axo-axonal synapses onto MBON04 ($\beta'2mp_bilateral$) as well as onto the atypical MBONs, MBON26 ($\beta'2d$) and MBON27 ($\gamma 5d$; indicated by the light orange shading in the output pie chart).

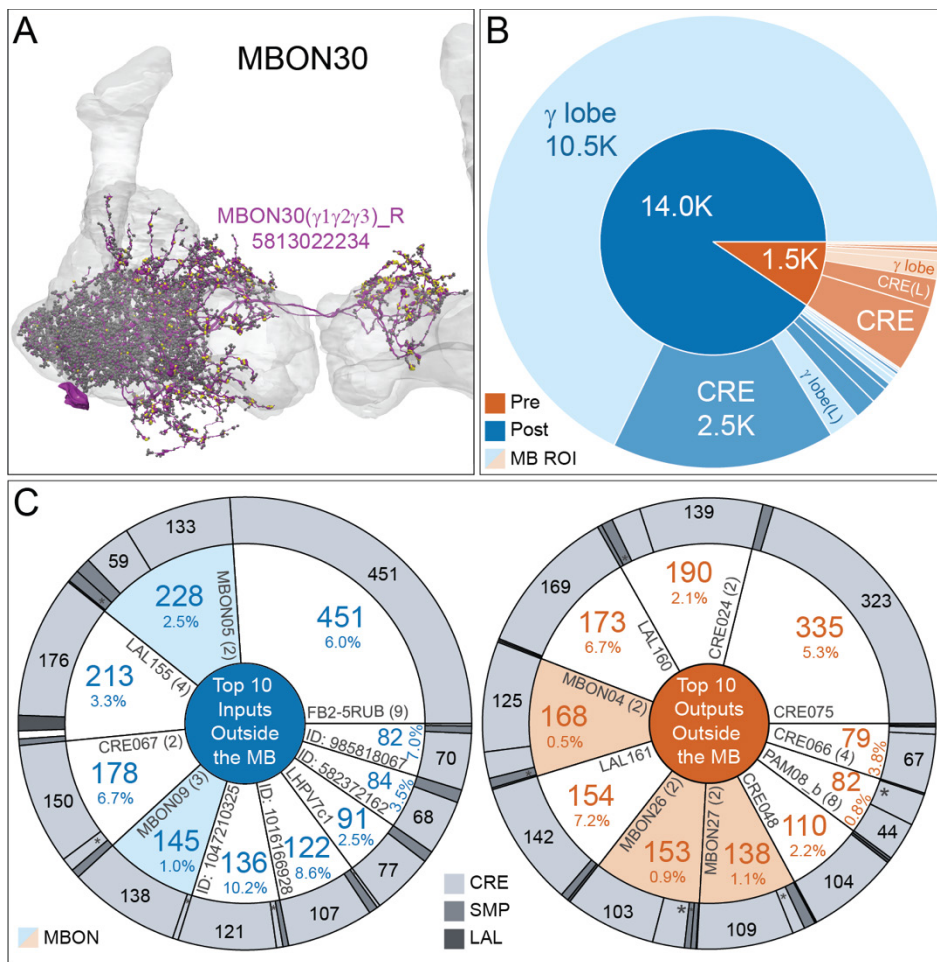

Figure 8-figure supplement 9. Atypical MBON30.

(A) Atypical MBON30 ($\gamma_1\gamma_2\gamma_3$) is shown here and in Video 15. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON30 receives about 80% of its input within the MB lobes, primarily from the γ_1 , γ_2 , and γ_3 compartments. (B) A pie chart showing the distribution of MBON30's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON30's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. The CRE is MBON30's major output area. (C) MBON30's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [FR1](#), [MBON05](#), [LAL155](#), [CRE067](#), [MBON09](#), [1047210325](#), [1016166928](#), [LHPV7c1](#), [582372162](#), and [985818067](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON30; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON30 gets strong input from nine fan-shaped body cells of cell type [FB2-5RUB](#) (FR1; collectively they make 451 synapses onto MBON30's arbors in a small brain area called the rubus (see Video 15). MBON30's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [CRE075](#), [CRE024](#), [LAL160](#), [MBON04](#), [LAL161](#), [MBON26](#), [MBON27](#), [CRE048](#), [PAM08_b](#), and [CRE066](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON30; the shading of the outer ring of the pie chart indicates where these synapses are located (asterisks indicate that these synapses are located in the left hemisphere). Note that MBON30 receives input from MBON05 ($\gamma_4 > \gamma_1\gamma_2$) and MBON09 ($\gamma_3\beta'1$) and makes synapses onto the atypical MBONs MBON27 (γ_5d) and MBON28 ($\alpha'3$) as well as to typical MBON04 ($\beta'2mp_bilateral$; indicated by the light blue and light orange shading in input and output pie charts, respectively).

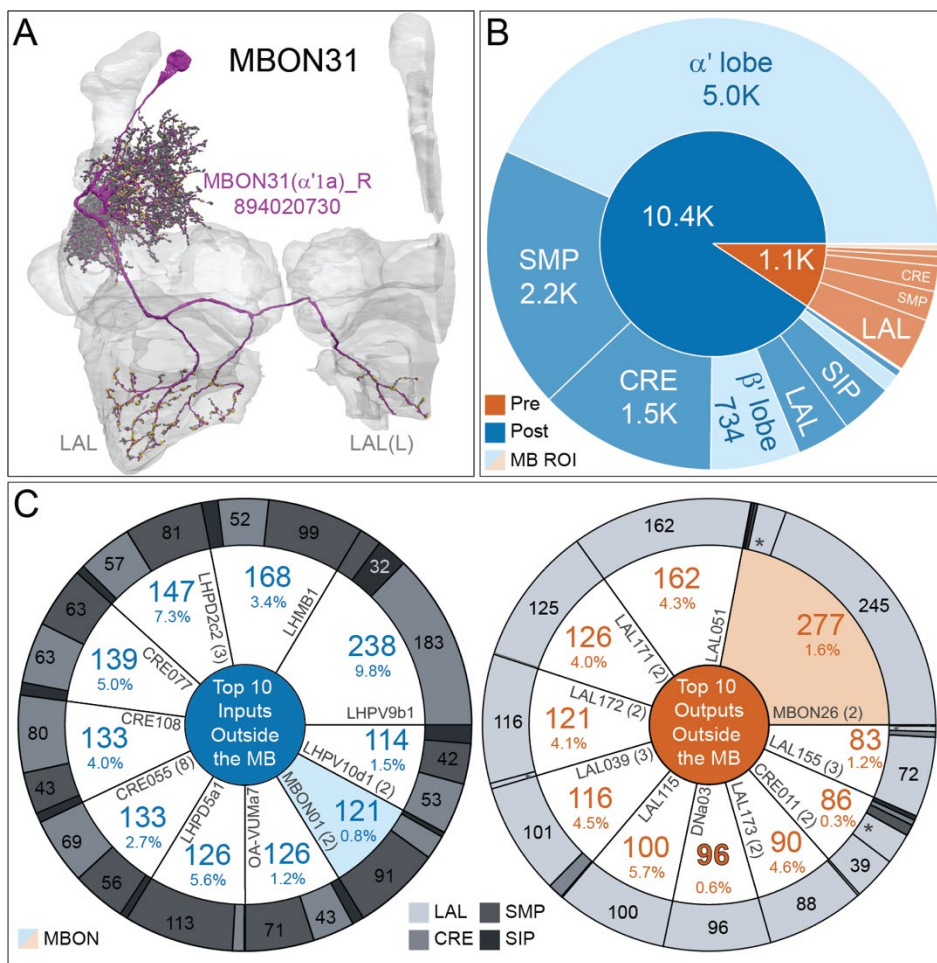

Figure 8- figure supplement 10. MBON31.

(A) Atypical MBON31 (α' 1) is shown here and in Video 16. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON31 gets about half of its inputs from the α' 1 compartment inside the MB and sends outputs to LAL. (B) A pie chart showing the distribution of MBON31's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON31's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON31's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [LHPV9b1](#), [LHMB1](#), [LHPD2c2](#), [CRE077](#), [CRE108](#), [CRE055](#), [LHPD5a1](#), [OA-VUMa7](#), [MBON01](#), and [LHPV10d1](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON31; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON31's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [MBON26](#), [LAL051](#), [LAL171](#), [LAL172](#), [LAL039](#), [LAL115](#), [DNa03](#), [LAL173](#), [CRE011](#), and [LAL155](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON31; the shading of the outer ring of the pie chart indicates where these synapses are located (asterisk indicates that these synapses are located in the left hemisphere). MBON31 top 10 inputs include five cell types that convey information from the LH and MBON01 (γ 5 β' 2a); its strongest downstream target is the atypical MBON, MBON26 (β' 2d).

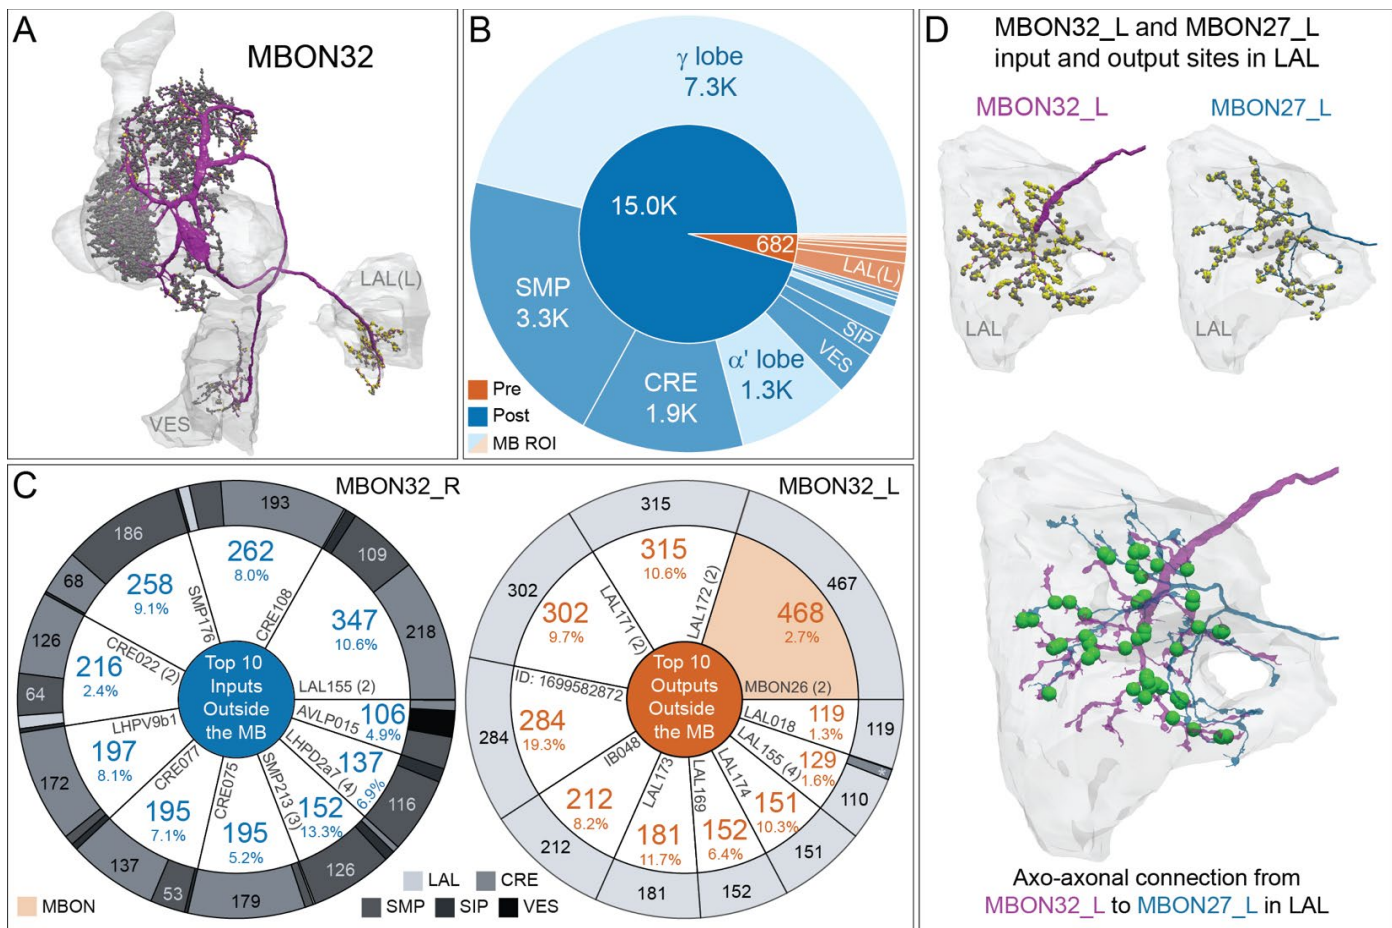

Figure 8-figure supplement 11. Atypical MBON32.

(A) Atypical MBON32 ($\gamma 2$) is shown here and in Video 17. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON32 gets about 50 percent of its synaptic input inside the MB lobes, primarily from the $\gamma 2$ compartment, and sends about half its output to the contralateral LAL. (B) A pie chart showing the distribution of MBON32's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON32's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON32's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [LAL155](#), [CRE108](#), [SMP176](#), [CRE022](#), [LHPV9b1](#), [CRE077](#), [CRE075](#), [SMP213](#), [LHPD2a7](#), and [AVLP015](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON32; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON32's axon targets the contralateral LAL and the left brain hemisphere is incomplete in the hemibrain volume; therefore, we used MBON32_L's arbors in the right hemisphere to ascertain MBON32's downstream targets. The top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [MBON26](#), [LAL172](#), [LAL171](#), [1699582872](#), [IB048](#), [LAL173](#), [LAL169](#), [LAL174](#), [LAL155](#), and [LAL018](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON32; the shading of the outer ring of the pie chart indicates where these synapses are located (asterisks indicate that these synapses are located in the left hemisphere). (D) We use the MBON32_L to illustrate MBON32's downstream targets in the right hemisphere LAL. MBON27 ($\gamma 5d$)'s axon also targets contralateral LAL (see Figure 8-figure supplement 6); the arbors of MBON32 and MBON27 in the LAL are shown separately in the upper portion of panel (D) with their pre- (yellow) and postsynaptic (grey) sites indicated. MBON32_L makes axo-axonal synapses onto MBON27_L, indicated by the green dots (lower portion of panel (D)).

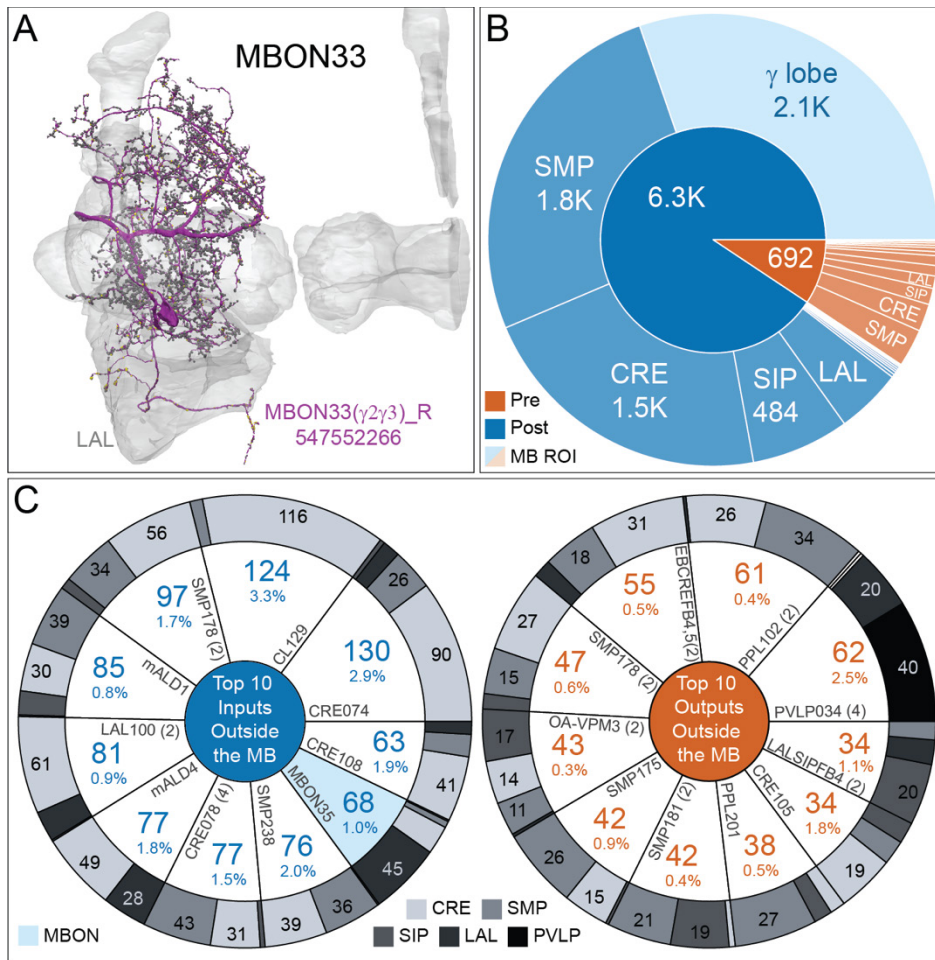

Figure 8-figure supplement 12. Atypical MBON33.

(A) Atypical MBON33 ($\gamma 2\gamma 3$) is shown here and in Video 18. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON33 gets about one-third of its input synapses within the γ lobe of the MB, mostly in the $\gamma 2$ and $\gamma 3$ compartments, and sends about 9% of its output to the LAL. (B) A pie chart showing the distribution of MBON33's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON33's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON33's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [CRE074](#), [CL129](#), [SMP178](#), [mALD1](#), [LAL100](#) (2), [mALD4](#), [CRE078](#), [SMP238](#), [MBON35](#), and [CRE108](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON33; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON33's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [PVLPO34](#), [PPL102](#), [EBCREFB4.5 \(FB4Y\)](#), [SMP178](#), [OA-VPM3](#), [SMP175](#), [SMP181](#), [PPL201](#), [CRE105](#), and [LALSIPFB4 \(FB4L\)](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON33; the shading of the outer ring of the pie chart indicates where these synapses are located.

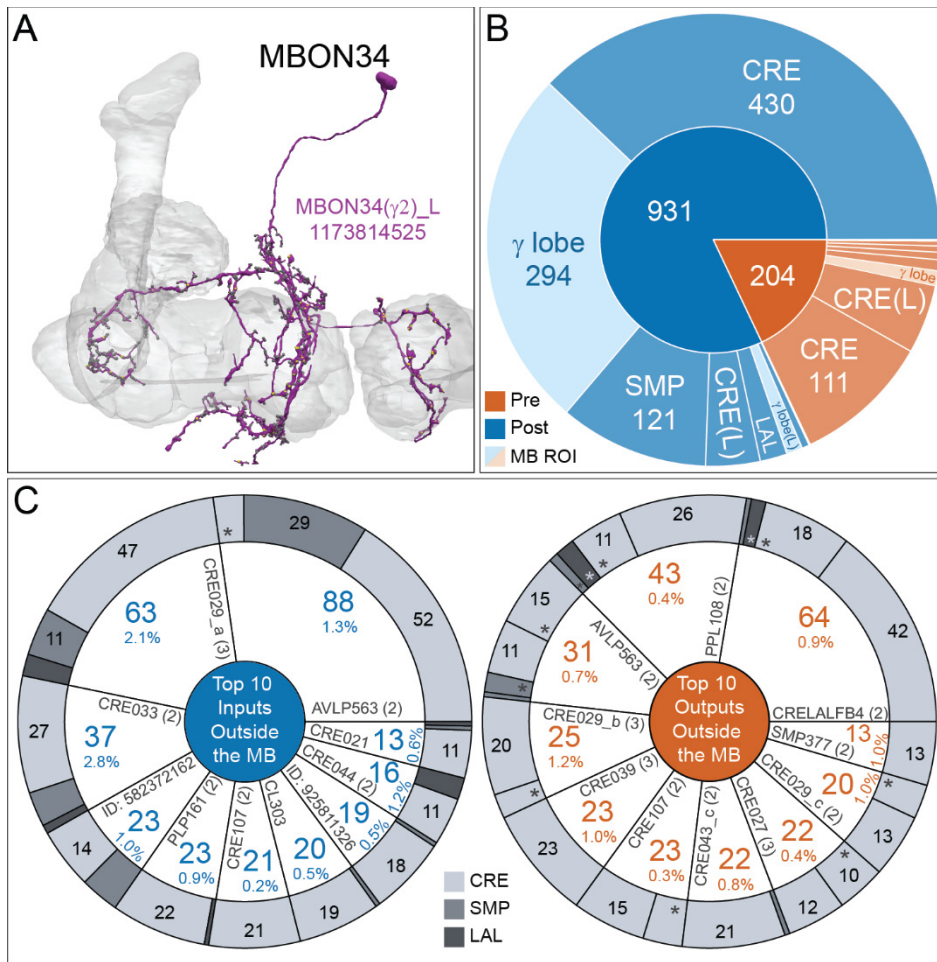

Figure 8-figure supplement 13. MBON34.

(A) Atypical MBON34 ($\gamma 2$) is shown here and in Video 19. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON34 has a small arbor and gets about one-third of its synapses from the $\gamma 2$ compartment inside the MB lobes. (B) A pie chart showing the distribution of MBON34's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON34's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON34's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [AVLP563](#), [CRE029_a](#), [CRE033](#), [582372162](#), [PLP161](#), [CRE107](#), [CL303](#), [925811326](#), [CRE044](#), and [CRE021](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON34; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON34's top ten by neuron type outputs outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [CRELALFB4_4](#) (FB4H), [PPL108](#), [AVLP563](#), [CRE029_b](#), [CRE039](#), [CRE107](#), [CRE043_c](#), [CRE027](#), [CRE029_c](#), and [SMP377](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON34; the shading of the outer ring of the pie chart indicates where these synapses are located (asterisks indicate that these synapses are located in the left hemisphere).

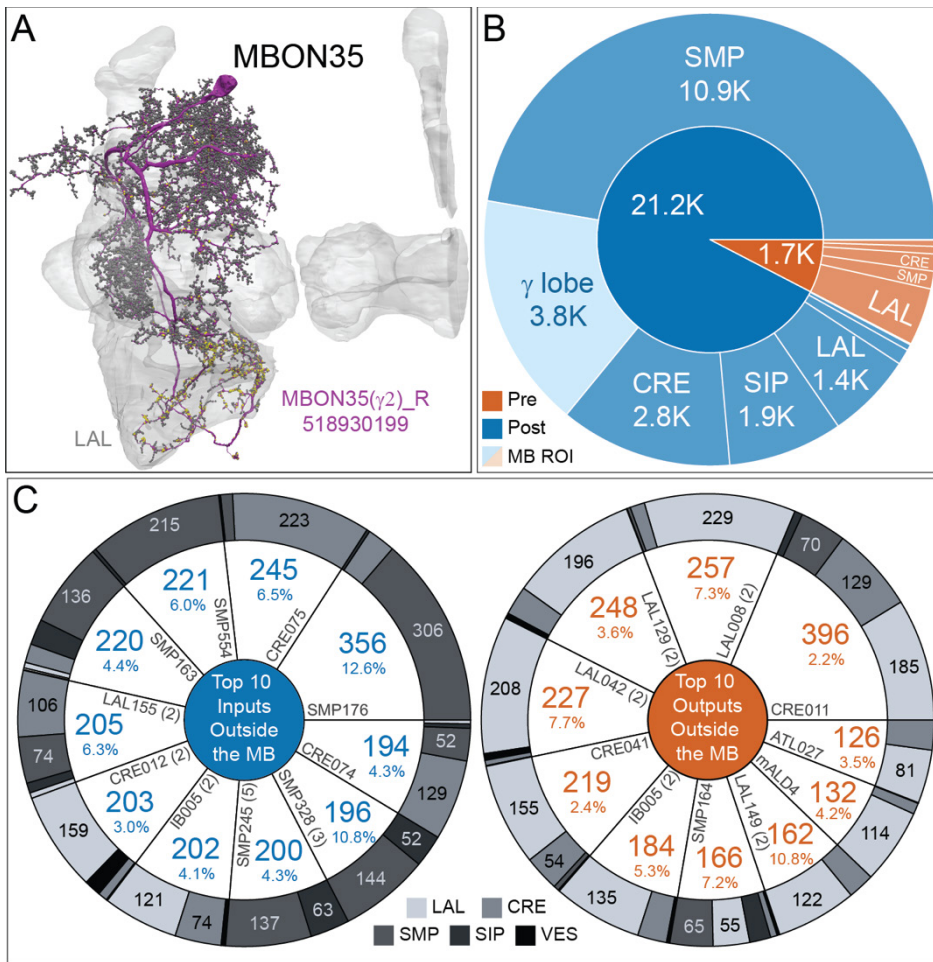

Figure 8-figure supplement 14. Atypical MBON35.

(A) Atypical MBON35 (γ 2) is shown here and in Video 20. Presynaptic sites are shown in yellow and postsynaptic sites are shown in grey. MBON35 gets about 20% of its input from the γ 2 compartment inside the MB lobes and sends about half its output to the LAL. (B) A pie chart showing the distribution of MBON35's presynaptic sites (indicated in orange) and postsynaptic sites (in blue). The inner circle shows the total number of MBON35's pre- and postsynaptic sites. The outer circle of the pie chart shows the brain regions in which these sites occur; regions of the MB are shown in lighter colors. (C) MBON35's top ten inputs by neuron type outside the MB lobes (left) are shown; links to these cell types in neuPrint are: [SMP176](#), [CRE075](#), [SMP554](#), [SMP163](#), [LAL155](#) (2), [CRE012](#), [IB005](#), [SMP245](#), [SMP328](#), and [CRE074](#). The numbers in each slice represent synapse numbers, while the percentages indicate the percentage of that neuron's synaptic output that goes to MBON35; the shading of the outer ring of the pie chart indicates where these synapses are located. MBON35's top ten outputs by neuron type outside the MB lobes (right) are shown; links to these cell types in neuPrint are: [CRE011](#), [LAL008](#), [LAL129](#), [LAL042](#), [CRE041](#), [IB005](#), [SMP164](#), [LAL149](#), [mALD4](#), and [ATL027](#). The numbers in each slice represent synapse numbers, while the percentages indicate the fraction of that neuron's input that is provided by MBON35; the shading of the outer ring of the pie chart indicates where these synapses are located.

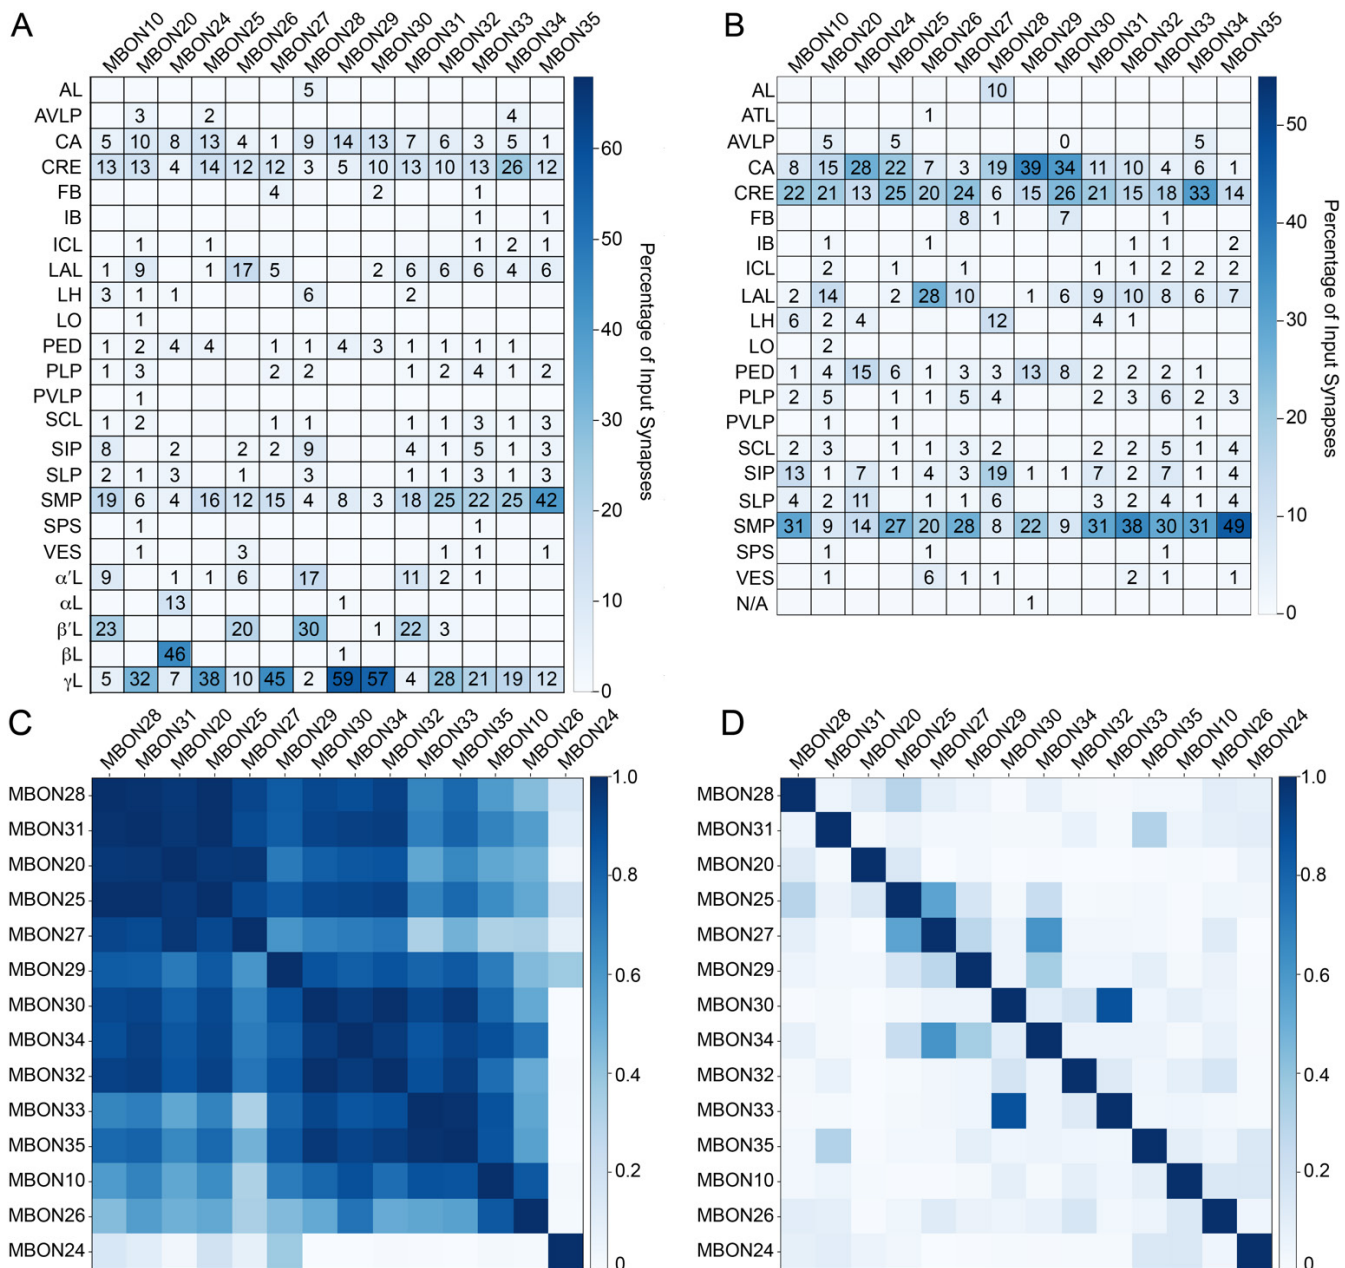

Figure 8-figure supplement 15. Atypical MBON input distribution by brain region and similarity of inputs to different MBONs.

(A-B) Distribution of brain regions providing input to atypical MBON types. The value in each box indicates the effective input to the indicated MBON from the indicated brain region; that is, based on where the neurons making synapses onto the MBONs get their own inputs. Effective input is a measure that takes into account both the strength of the connection of each of the neurons that provides input to the MBON and the connection strength of other neurons to each of those input neurons in each brain region. Effective input is computed by matrix-multiplying the inputs to the MBONs and the inputs to those MBON-presynaptic neurons (normalizing both matrices so that inputs to all neurons sum to 1). Blank boxes indicate values of less than 1%. Input received inside MB lobes is included in A and excluded in B. (C) Cosine similarity between MBON types based on their input at the level of brain regions, with the MB excluded. (D) Cosine similarity between each MBON based on their inputs, with the MB excluded and the computation of the degree of input overlap performed at the level of individual presynaptic neurons. The ordering of MBONs in C and D was determined using spectral clustering.

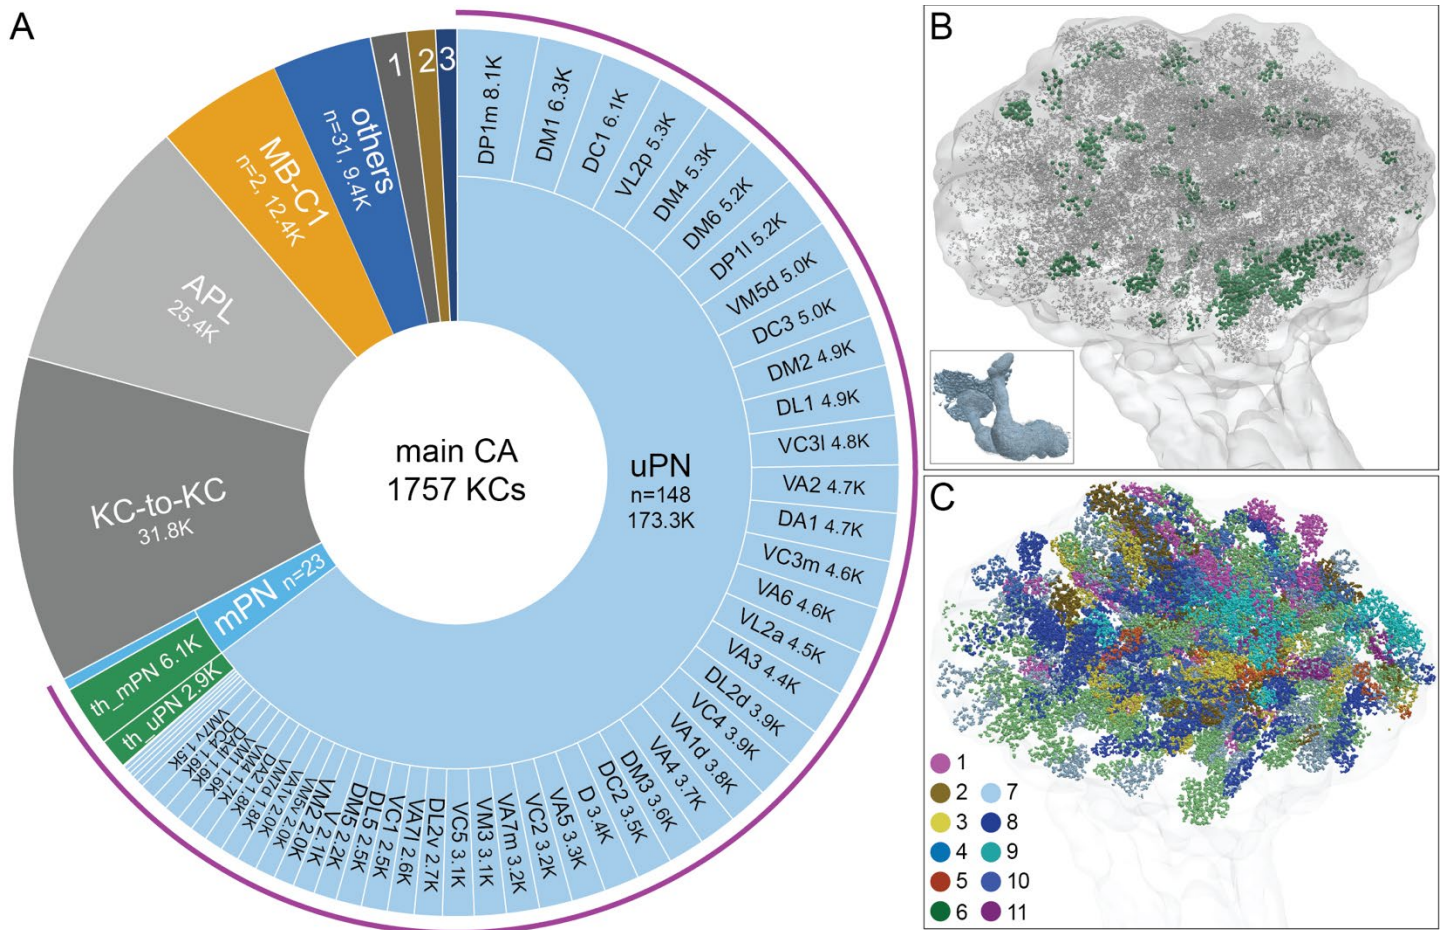

Figure 9. Main calyx (CA).

The dendrites of 1757 KCs of the α/β , α'/β' and γ cell types define the CA. (A) The pie chart shows a breakdown of the inputs to these KCs. The largest source of input is from 129 uniglomerular olfactory projection neurons as judged by synapse number (uPNs; 63.6% of total input to the KCs); the number of synapses is indicated for each uPN cell type. Additional olfactory sensory input is provided by 23 multiglomerular projection neurons (mPNs). Information about temperature is provided by both 35 mPNs (th_mPN) and 19 uPNs (th_uPN). The next most prominent inputs are KC-to-KC synapses within the CA (11.9%), from APL (9.5%; see Figure 3-figure supplement 1A) and from MB-C1 (4.6%; see Figure 3-figure supplement 1H). Smaller sources of input are indicated by the numbered sectors: 1, a group of 9 neurons previously described as “centrifugal” neurons (Bates et al., 2020) that innervate both CA and LH (1.3%). 2, [MB-CP2](#) (1.0%); 3, [PPL201](#) (see Figure 3-figure supplement 1G). The remaining 3.4% is provided by 31 other neurons (blue). (B) An image of the CA showing the locations of olfactory PN and thermo PN synapses onto KCs. The green dots representing thermo PN olfactory input synapses are of larger diameter to allow better visibility in the presence of the larger number of grey dots representing olfactory input synapses. Note the thermo PN inputs are located in the anterior and at the periphery of the CA, corresponding to the position of α'/β' ap1 and γ t KC dendrites. The inset shows the orientation of the image. (C) Inputs from olfactory PNs are shown color-coded based on the type of olfactory information they are thought to convey (see Bates et al., 2020): 1, fruity; 2, plant matter; 3, animal matter; 4, wasp pheromone; 5, insect alarm pheromone; 6, yeasty; 7, alcoholic fermentation; 8, decaying fruit; 9, pheromonal; 10, egg-laying related. 11. geosmin.

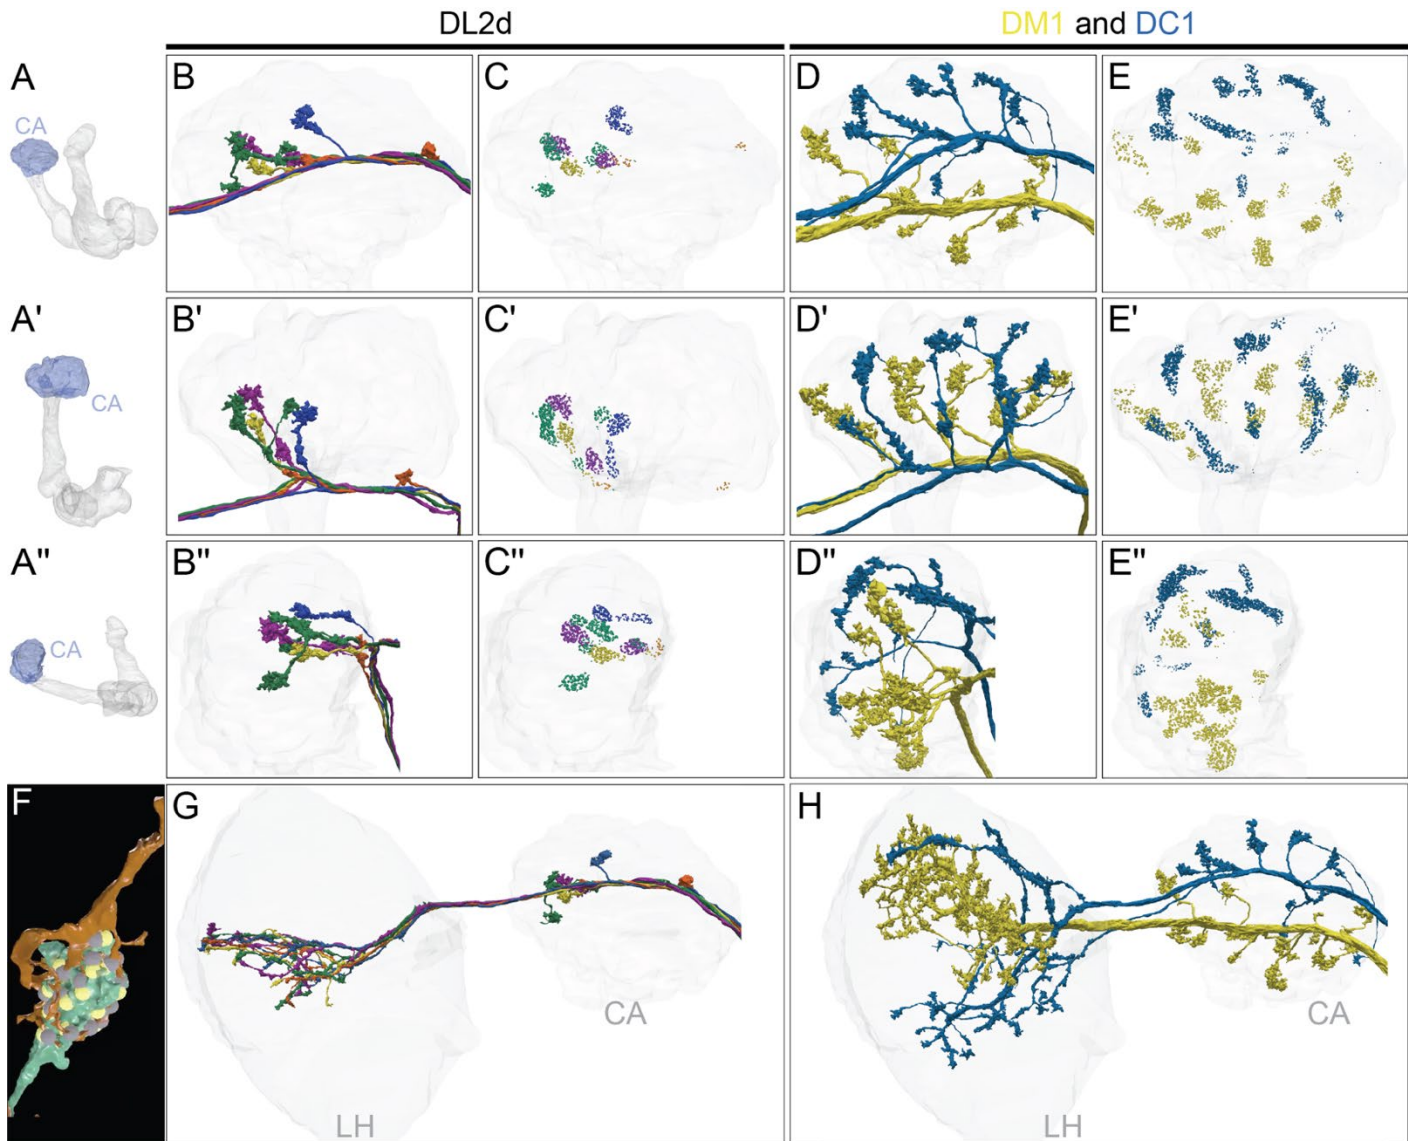

Figure 9-figure supplement 1. Distribution of the termini of olfactory PNs in the CA.

(A-A'') MB images showing the orientation of the CA (blue) in panels B-E'': (A) frontal view. (A') top view. (A'') side view. (B-B'') Four individual DL2d uniglomerular PNs (uPNs), each shown in a different color, innervate the CA, shown in faint grey. The axons of individual PNs split into two to three branches, each terminating in a large bouton that forms part of a highly stereotyped “claw-like” synapse with the KCs (F; Video 21). DL2d PNs terminate primarily in the anterior-lateral CA. (C-C'') Synaptic connections, color-coded to correspond to the PNs in B-B'', from DL2d PNs onto KCs. (D-D'') DM1 and DC1 are shown; these uniglomerular PNs are unusual in that there is only a single cell of each type per brain hemisphere. Both DM1 and DC1 have widely distributed boutons, which occupy non-overlapping areas of the CA (Jeanne et al., 2018); DM1's boutons are more dorsal and DC1's more ventral. (E-E'') Synaptic connections from the DM1 and DC1 PNs onto KCs, color-coded by PN type. (F) An example PN to KC synapse with a claw-like structure. [DA1 IPN](#) (1734350908; green) connects to [KCym](#) (600356751; Video 21; orange); note how the KC dendrite wraps around the PN bouton. Presynaptic sites of the PN and postsynaptic sites of the KC are shown in yellow and grey respectively. (G-H) Distribution of the axons of DL2d, DM1 and DC1 in the LH and CA. (G) The four DL2d PNs innervate the middle of the LH. Note their axons terminate in the same area of the LH, but lack the large terminal boutons seen in the CA. (H) DM1 and DC1 axons remain segregated in the LH.

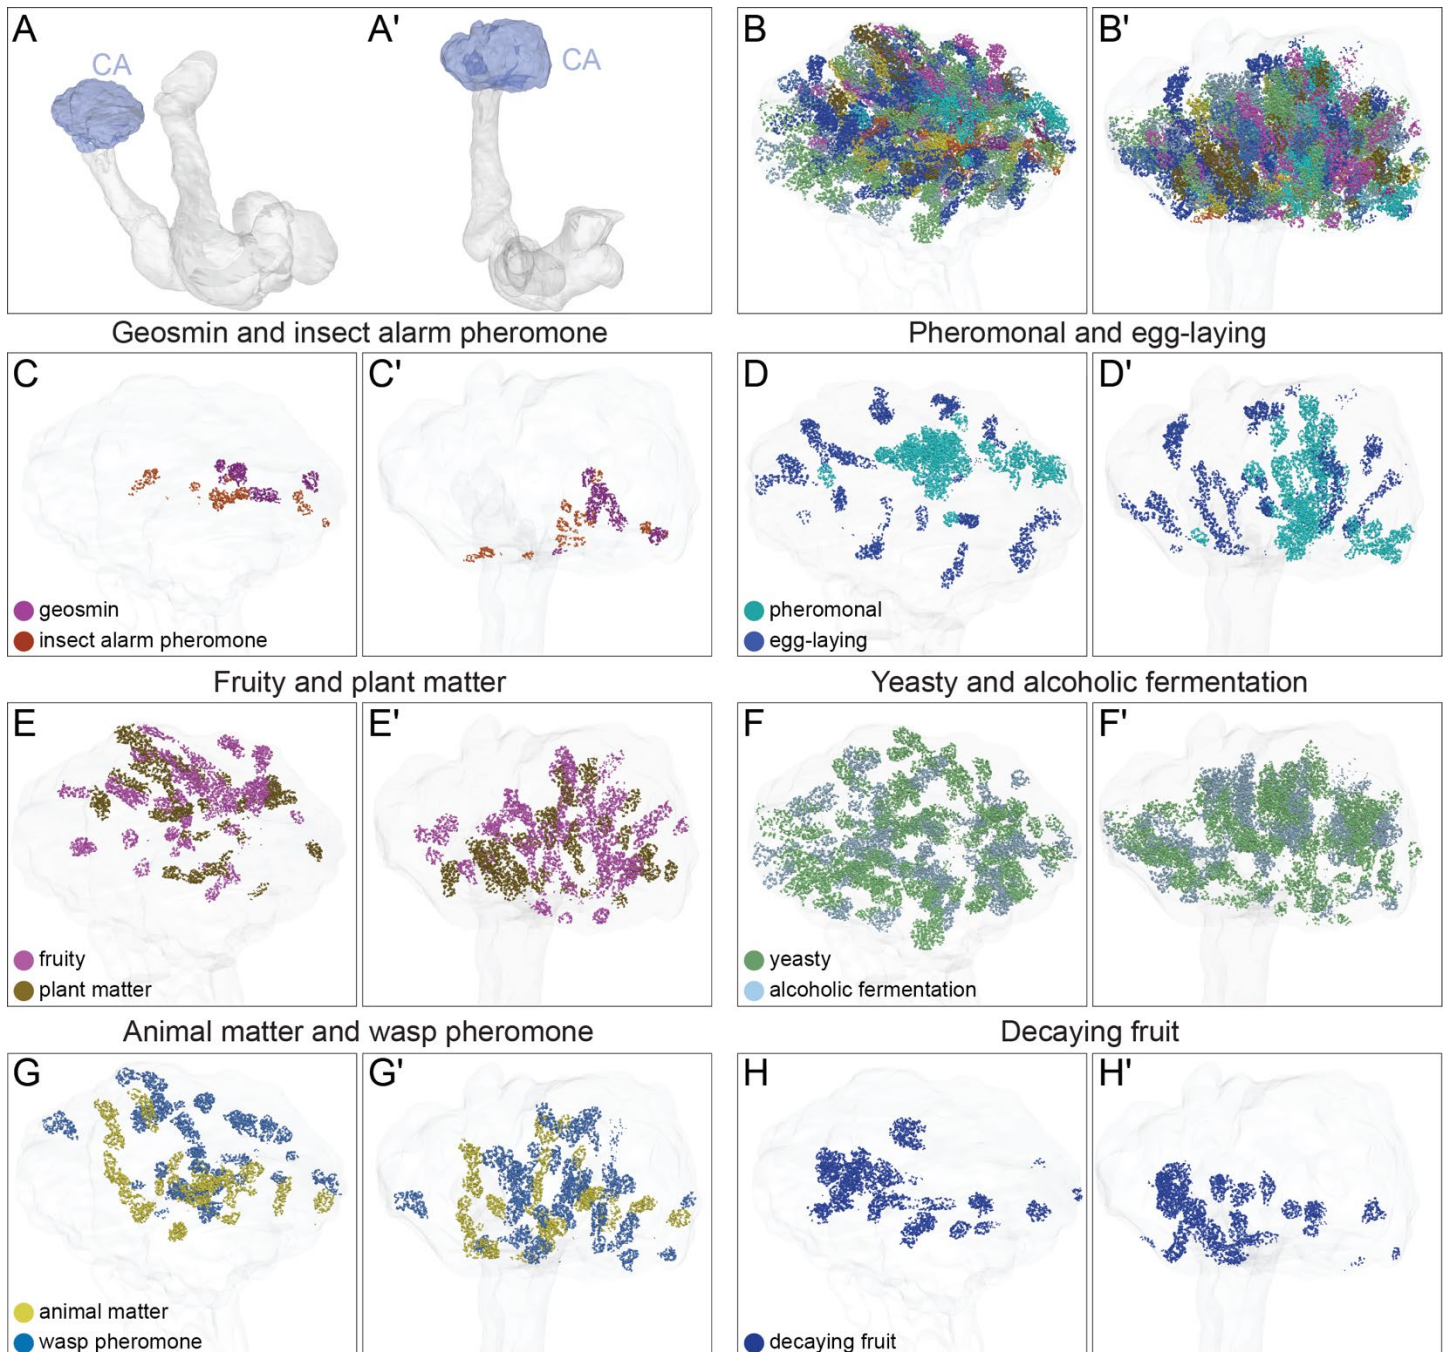

Figure 9-figure supplement 2. Spatial arrangement in the CA of synaptic input from different PN groups. The synaptic terminals of PNs in the CA are shown. PNs that convey distinct types of olfactory information are shown separately as indicated. (A, A') MB images indicating the orientation of the figures shown in remaining panels: (A) frontal view; (A') top view. The CA is shaded blue. (B, B'). Synapses KCs receive from all the olfactory PN groups that are shown individually in panel C-H'. (C, C') PNs that convey the presence of geosmin and insect alarm pheromone, both highly aversive odors, are clustered. (D, D') PNs that convey pheromones and odors involved in egg-laying site selection occupy the center and periphery of the CA, respectively. (E, E') PNs that convey fruity and plant matter information are distributed in the dorsal part of the CA. (F, F') PNs that convey yeasty and alcoholic fermentation odors are distributed widely across the CA. (G, G') PNs that convey wasp pheromone and animal matter information. (H, H') PNs that convey decaying fruit information.

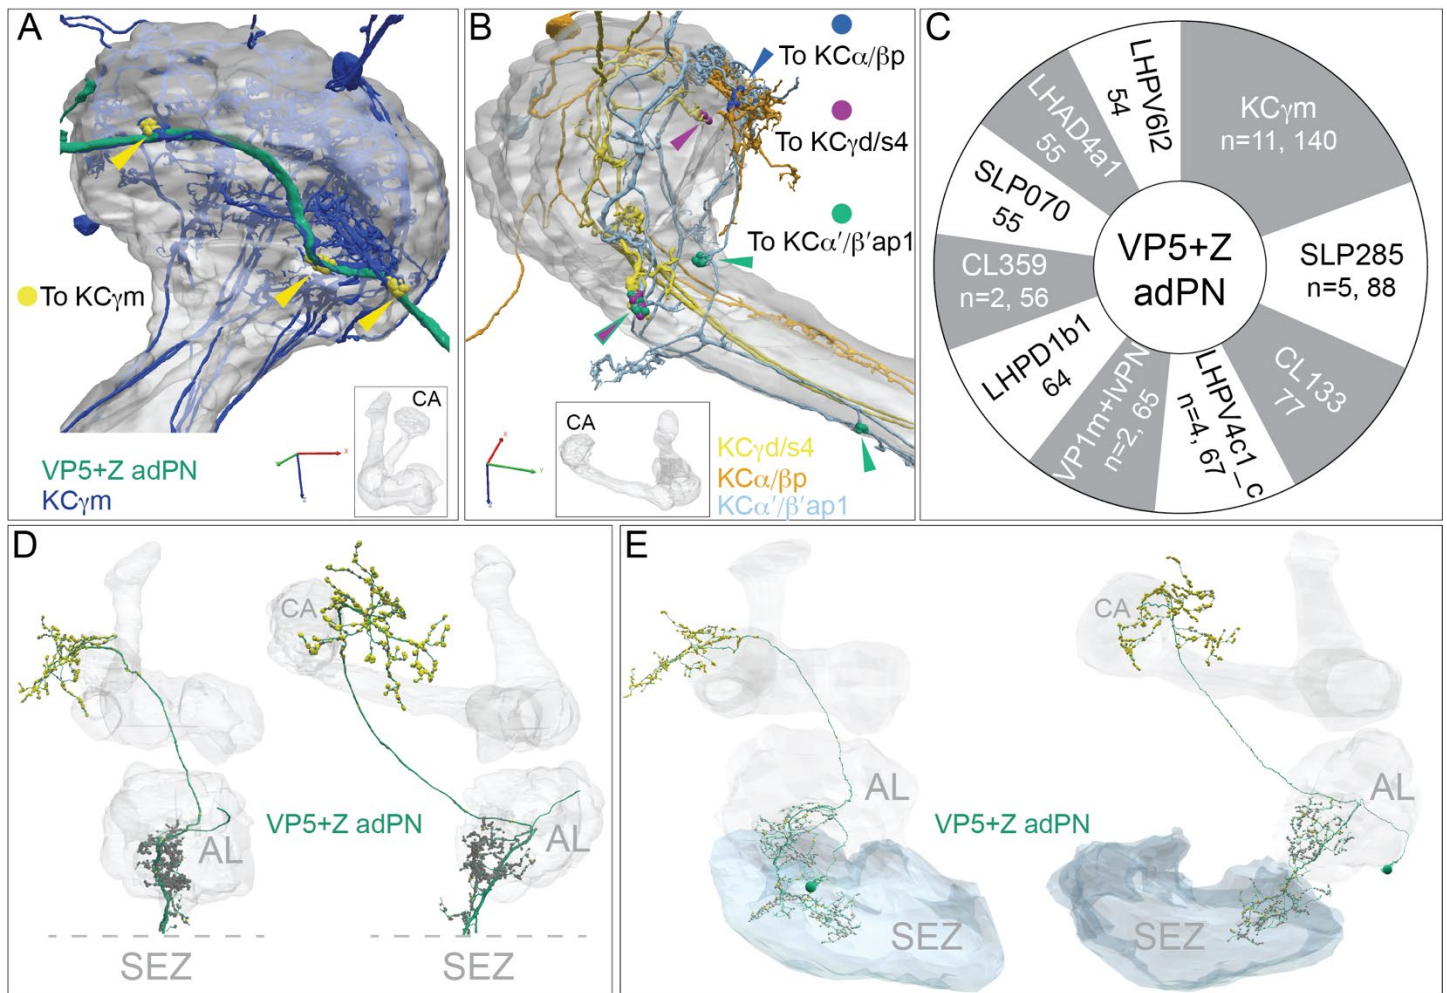

Figure 9-figure supplement 3. Gustatory input to a subset of KCs.

The PN, [VP5+Z adPN](#), has been reported to receive sensory input with mixed modalities, with hygrosensory input from the VP5 glomerulus in the AL and gustatory input from the SEZ (Marin et al., 2020). We found that it connects to 16 KCs that extend a portion of their dendritic arbors outside the main CA. (A) [Eleven \$\gamma\$ m](#) KCs connect at three locations to the axon of VP5+Z adPN, just anterior to the main CA (indicated by yellow arrowheads), forming a total of 140 synapses. The same 11 γ m KCs also have dendritic claws inside the CA (their dendrites are dark blue where they lie outside the CA and faint blue where they lie within the CA) where they receive input from many [olfactory PN](#) types; their synapses from VP5+Z adPN do not have a claw-like structure. VP5+Z adPN is the top PN input to these KCs. (B) Connections from VP5+Z adPN to other KC types are shown: [three KC \$\gamma\$ d/s4](#) (purple, n=30); [two KC \$\alpha\$ / \$\beta\$ p](#) (green, n=13) and [two KC \$\alpha\$ '/ \$\beta\$ 'ap1](#) (blue, n=12). (C) Top 10 downstream targets of VP5+Z adPN by neuron type. Note that the 11 γ m KCs are its top target. (D) VP5+Z adPN in the hemibrain (left: front view, right: side view) with presynaptic sites shown in yellow and postsynaptic sites in grey. Note the SEZ is not in the hemibrain volume and its putative position is indicated below the dashed lines, which mark the ventral extent of the hemibrain volume. (E) VP5+Z adPN traced in FAFB, with its complete dendrite in the SEZ where it receives strong input from gustatory receptor neurons (S. Engert and K. Scott, personal communication). The same two views as in panel D are shown; presynaptic (yellow) and postsynaptic (grey) sites are indicated.

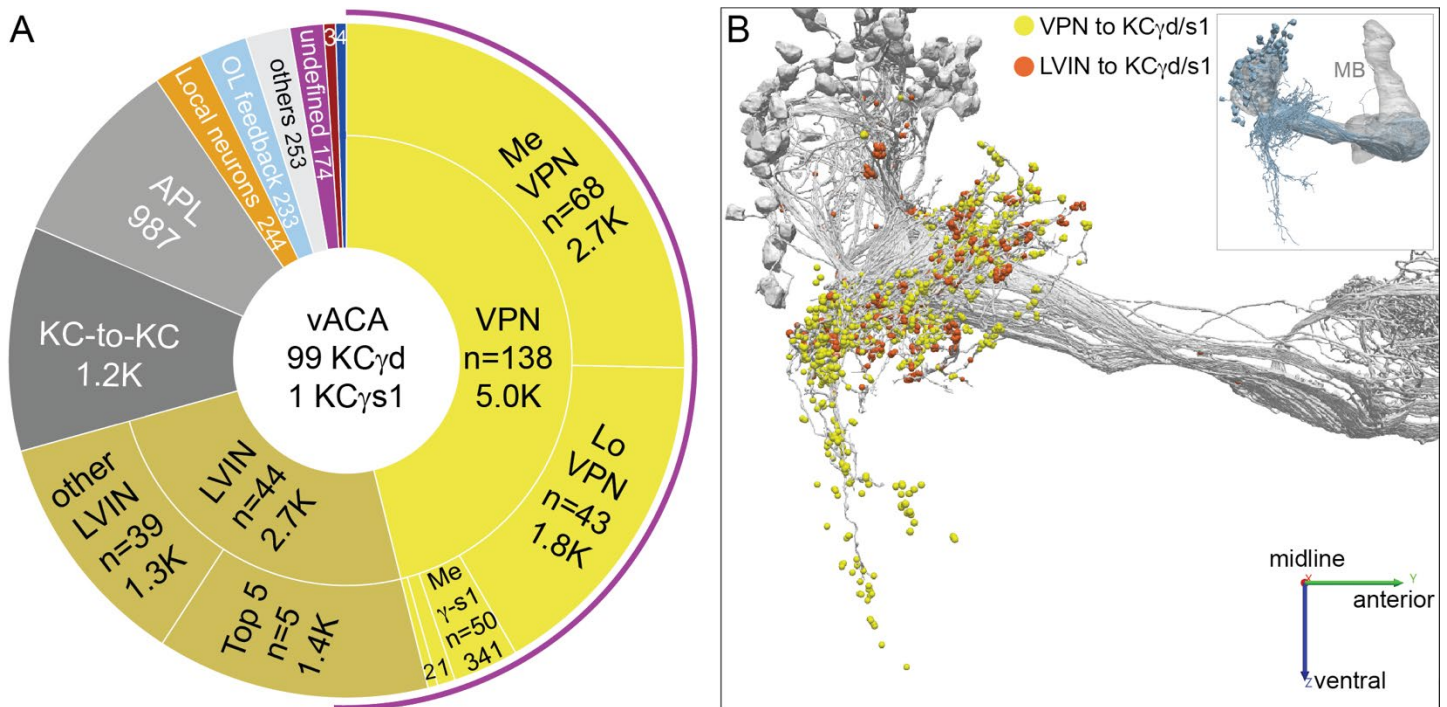

Figure 10. Ventral accessory calyx (vACA).

The dendrites of the 99 γd and $\gamma s1$ KCs define the vACA. (A) The pie chart shows a breakdown of the inputs to these KCs; the number of cell (n=) and the number of the total synapses contributed by the cells in that sector are shown without applying a threshold. The majority of inputs convey visual information, either directly from visual projection neurons (VPNs; 46.1%) or through intermediate local visual interneurons (LVIN; 24.6%) that themselves receive input from VPNs. The number of VPNs shown in pie chart counts VPNs that make as few as one synapse. When a threshold is applied that requires a VPN to make at least 5 synapses to a single KC, then we find 49 VPNs, including 26 ME VPNs and 21 LO VPNs. The synapses from the VPNs and the LVINs onto the $KC_{\gamma d}$ dendrites do not show the claw-like structure seen in the CA (Video 22). A ranking of LVINs based on the amount of visual input conveyed is shown in Figure 10-figure supplement 1A. More than half of the indirect input is mediated by five LVINs (Top 5), which are shown in Figure 10-figure supplement 3B. VPNs can be subdivided based on the location of their dendrites in either the medulla (ME) or lobula (LO), as indicated in the outer circle. There are 68 VPNs that connect to the single $KC_{\gamma s1}$, with a total of 483 synapses: 50 from the Me, 34 of which are shared with other γd KCs, and 14 from the LO, eight of which are shared with other γd KCs (represented by the numbered sector 1). The next most prominent inputs to KCs in the vACA are synapses between the KCs themselves (10.8%), from APL (9.1%), from local interneurons that do not appear to convey significant visual information (2.3%), from interneurons that send feedback from the vACA to optic lobe neurons (OL feedback; 2.2%) and neurons that leave the volume with undefined identity (undefined; 1.6%). Other sources of input are indicated by the other numbered sectors: 2, other VPN input that we could not classify as from the Me or Lo, due to incomplete morphology (0.9%); 3, [putative mPNs](#) (0.6%) (5813063239, 1442819296, 5813040515); 4, a [putative SEZ cell type](#) (0.5%). The remaining 2.3% is provided by 253 interneurons that are weakly connected to these KCs, with each providing 1 synapse to each of less than 4 KCs (others). The fraction of input to the vACA KCs conveying visual information is indicated by the outer purple arc; it reflects the direct input from the VPNs plus the fraction of the LVIN input that represents visual input. (B) Synaptic connections from visual projection neurons (VPN) and local visual interneurons (LVIN) onto γd and $s1$ KCs (grey), color-coded. Note the different spatial distribution of synapses from VPNs and LVINs. VPNs make synapses onto $KC_{\gamma d}$ dendrites in an area ventral to the CA, previously recognized as the vACA (Butcher et al., 2012), as well as in a diffuse ring surrounding the base of the CA; synapses from LVINs are restricted to the ring. Additional views are shown in Figure 10-figure supplement 4A and B.

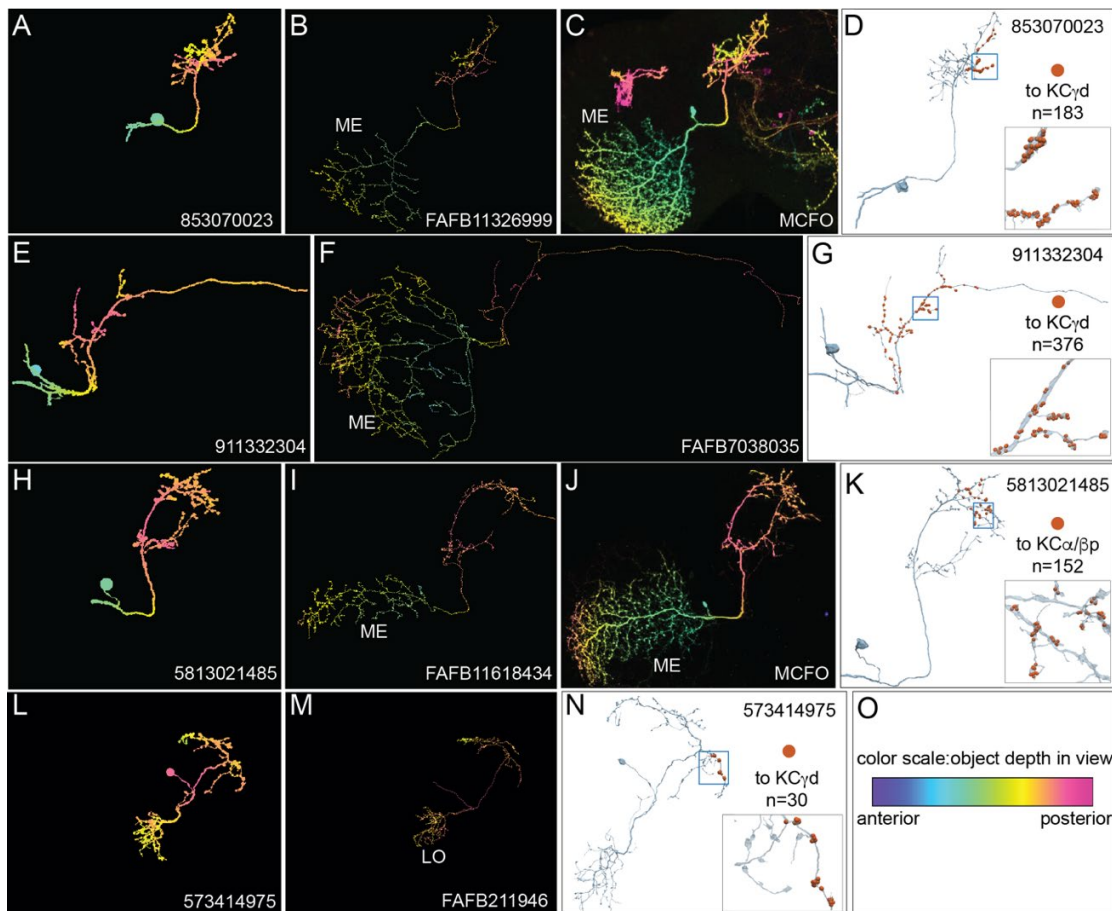

Figure 10-figure supplement 1. Identification of VPNs.

The arbors of the ME VPNs generally extend into portions of the optic lobes that are not contained in the hemibrain volume. In order to determine the locations in the optic lobes where their dendrites are located, we relied as much as possible on matching the portion of their neuronal arbors contained in the hemibrain with morphologies of complete neurons from two other datasets: neurons that we traced in FAFB (Zheng et al., 2018) or light microscopic images of single neurons derived using Multi-Color Flip-Out (Nern et al., 2015) of GAL4 lines. In other cases, we based our classification on the similarity of the morphology of the neuron to other VPNs and the position where its arbor left the hemibrain volume. This figure shows three examples of matching ME VPNs to their putative FAFB and MCFO counterparts (A-K) and one example showing an LO VPN that is totally contained within the hemibrain volume (L-N). The images shown in panels A-C, E, F, H-J and L, M are maximum intensity projections in which the color of the neuronal arbors reflects their anterior-posterior depth in the brain (see scale in panel O; Bailey and Clark, 1998; Ropinski et al., 2006; Otsuna et al., 2018). (A-C) An example of a ME VPN innervating the vACA from the hemibrain (A) and its likely equivalents in FAFB (B) and MCFO light data (C). (D) The reconstructed neuron from the hemibrain showing the positions on its axon of the 183 synapses that it makes onto a total of 20 γ d KCs indicated by the orange dots; inset, enlarged view of the boxed area. (E-F) A second example of a vACA-innervating ME VPN from the hemibrain dataset (E) and its likely match in FAFB (F). (G) The reconstructed neuron from the hemibrain with the positions on its axon of the 376 synapses that it makes onto a total of 27 γ d KCs and the single γ s KC indicated by the orange dots; inset, enlarged view of the boxed area. (H-J) An example of a dACA-innervating ME VPN (H) and its likely matches in FAFB (I) and MCFO (J). (K) The reconstructed neuron from the hemibrain showing the positions on its axon of the 152 synapses it makes onto a total of 41 α/β KCs; inset, enlarged view of the boxed area. (L-N) A vACA-innervating Lo VPN (L) and its likely matches in FAFB (M). Note how the entire arbor appears to be present in the hemibrain. (N) The reconstructed neuron from the hemibrain showing the positions on its axon of the 30 synapses that it makes onto a total of 2 γ d KCs; inset, enlarged view of the boxed area. (O) Color-depth scale.

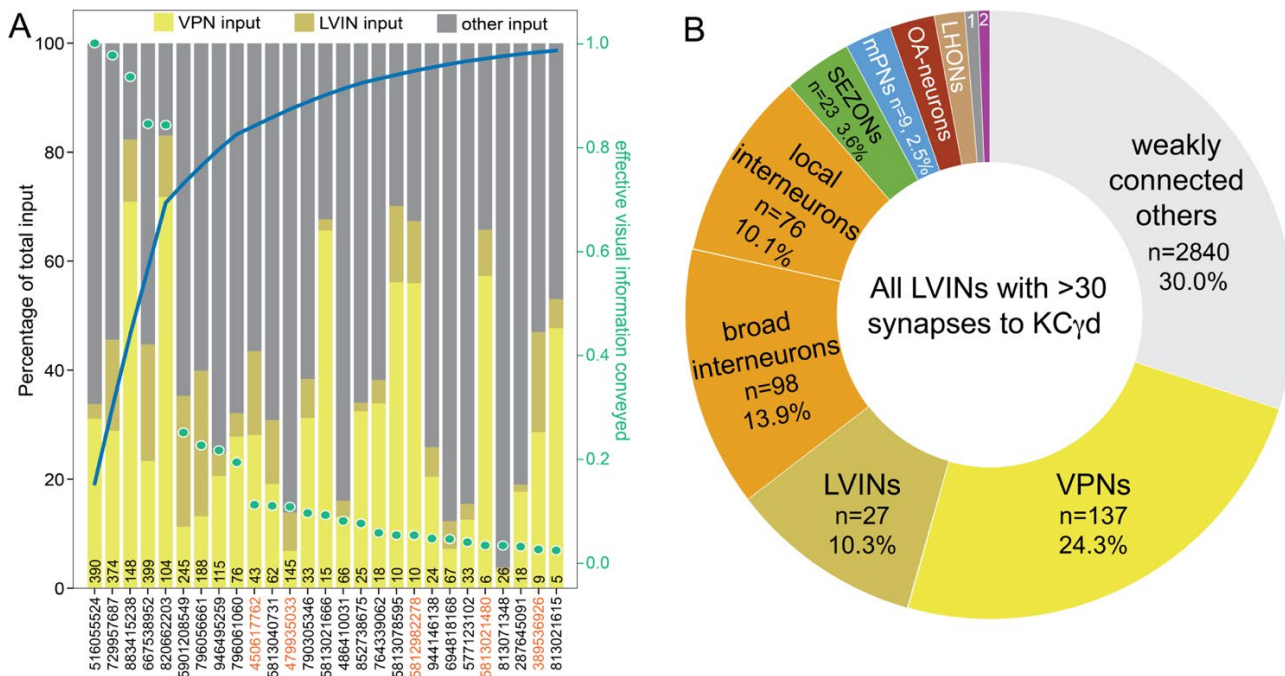

Figure 10-figure supplement 2. LVINs ranked by amount of visual information conveyed.

(A) Plot of interneurons carrying visual information to the γ_d and γ_{s1} KCs ranked by the strength of their effective contribution of visual information. For a given interneuron, this quantity is computed by multiplying the number of synapses that interneuron makes onto γ_d and γ_{s1} KCs by the fraction of its input synapses that come from visual projection neurons. The green dots show this effective visual information quantity. Values are normalized to the most strongly connected LVIN, which was assigned a value of 1.0 (green scale on the right side of the plot). The blue line shows the cumulative amount of effective visual information conveyed by LVINs; over 80% of the input is delivered by the top ten LVINs. Links to these 10 LVINs in neuPrint are as follows: [CL063](#), [PLP095](#), [PLP145](#), [PLP120](#), [CL258](#), [CL200](#), and [AVLP043](#). The color-coded bars indicate the percentage of that neuron's input that comes from VPNs, other LVINs, and other neurons. The black number at the base of each bar shows the number of synapses made by that LVIN to KCs in the vACA. The LVINs whose ID numbers are shown in orange also provide input to the α/β_p KCs in the dACA. Note that many of the lower ranked LVINs that receive high levels of VPN input do not make strong connections to KCs and are therefore presumably primarily performing some other role in integrating visual information. (B) Effective input delivered by the 15 LVINs that are the most strongly connected to the 99 γ_d and one γ_{s1} KCs that are found in the vACA; each of these LVINs makes a total of 30 or more synapses to vACA KCs. Effective input is calculated by multiplying the indicated neuronal population's synaptic input to each of the 15 LVINs times the fraction of the 99 γ_d and one γ_{s1} KCs' total input coming from that LVIN, and then summing across all 15 LVINs. Effective input is expressed as the percentage of the total input from these 15 LVINs to the 99 γ_d and one γ_{s1} KCs that originated with the indicated neuronal population. To calculate the values presented, we considered the 408 neurons that collectively account for 70% of the total input synapses to these 15 LVINs and placed them into the categories shown in the pie chart; we did not attempt to classify the large number of diverse neurons (weakly connected others) that make up the other 30% of the input. VPNs, at 24.3%, provide the strongest category of effective input to vACA KCs mediated by LVINs. This visual input is in addition to direct input that VPNs make onto the dendrites of the vACA; taking the direct and indirect pathways together, more than half the total input, and ~70% of the sensory input to the vACA is visual. We classified interneurons that did not receive visual input as local if their arbors were confined to the brain area around the vACA, as we observed for the LVINs, or broad, if they arborized in several brain areas. Although there is no direct input to γ_d or γ_{s1} KCs from the SEZ, a group of 13 putative [SEZONS](#) contributes 2.6% of the LVINs effective input. Other inputs include [OA neurons](#) (n=6, 2.4%), [LHONs](#) (n=22, 1.6%), [5-HT neurons](#) (n=6, 0.7%; numbered sector 1), and APL and DPM (0.6% combined; numbered sector 2).

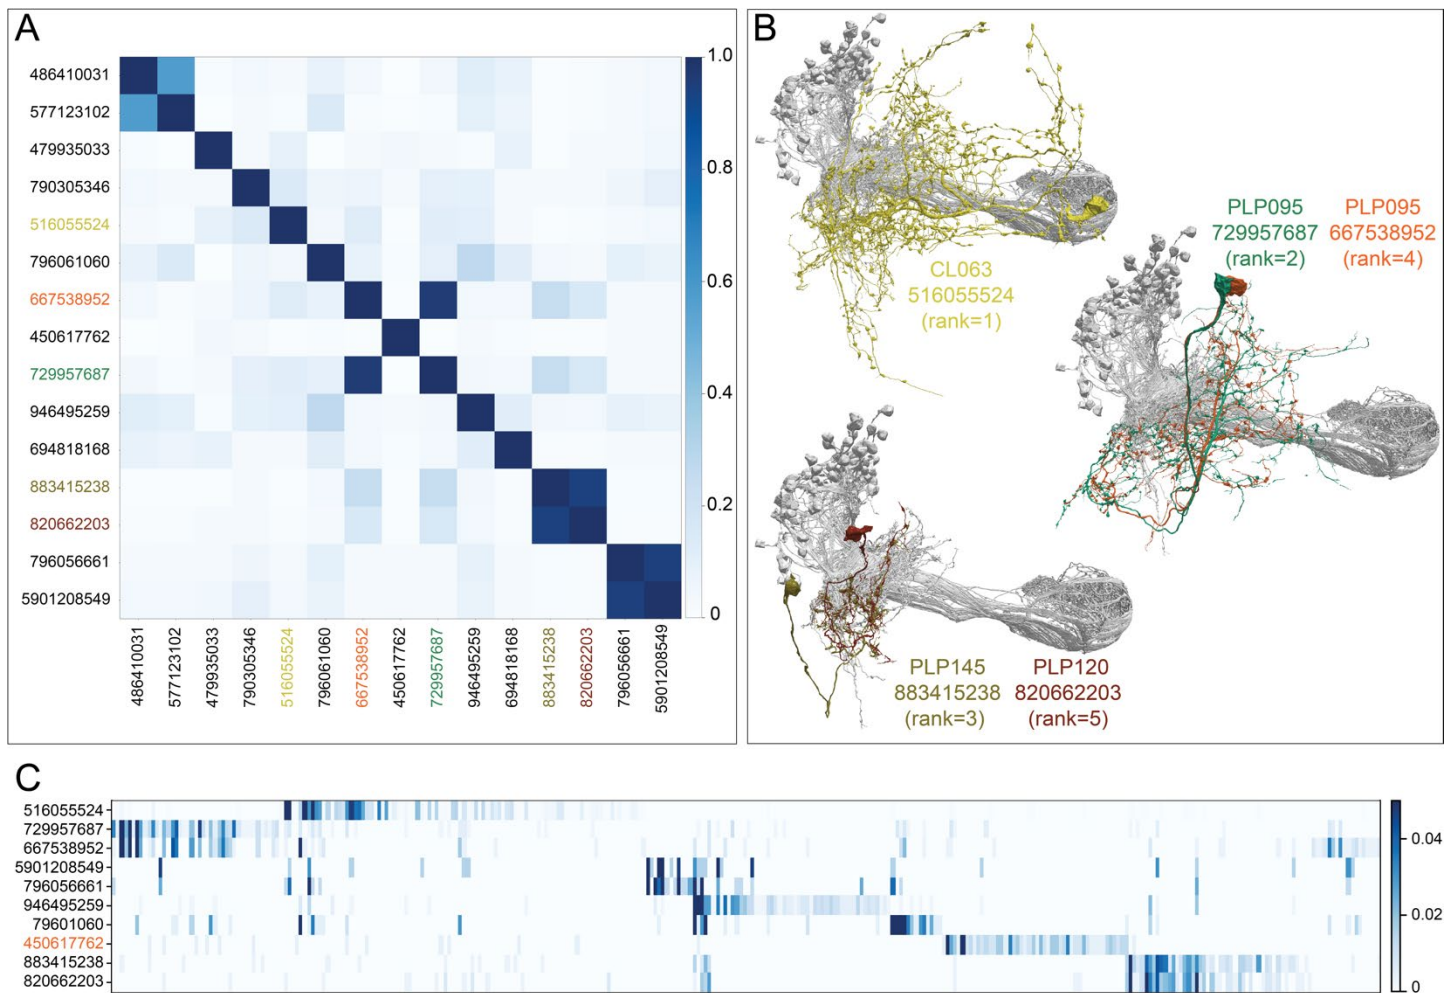

Figure 10-figure supplement 3. Further description of LVINs upstream of vACA KCs.

(A) A plot showing the similarity of the 15 LVINs most strongly connected to the vACA KCs, based on the cosine similarity of their inputs. The neuron IDs are color coded to match the morphologies shown in (B). (B) The morphologies of the top five LVINs are shown; KCs are in grey. The orientation of the images is the same as in the inset shown in Figure 10B. (C) A plot showing the VPN inputs for each of the top ten LVINs, using the ranking of effective visual input from Figure 10-figure supplement 1A. Each vertical blue bar represents a different VPN and the intensity of the color reflects the fraction of the corresponding LVIN's total VPN input that is contributed by that VPN. The order of the VPNs and LVINs is determined using spectral clustering.

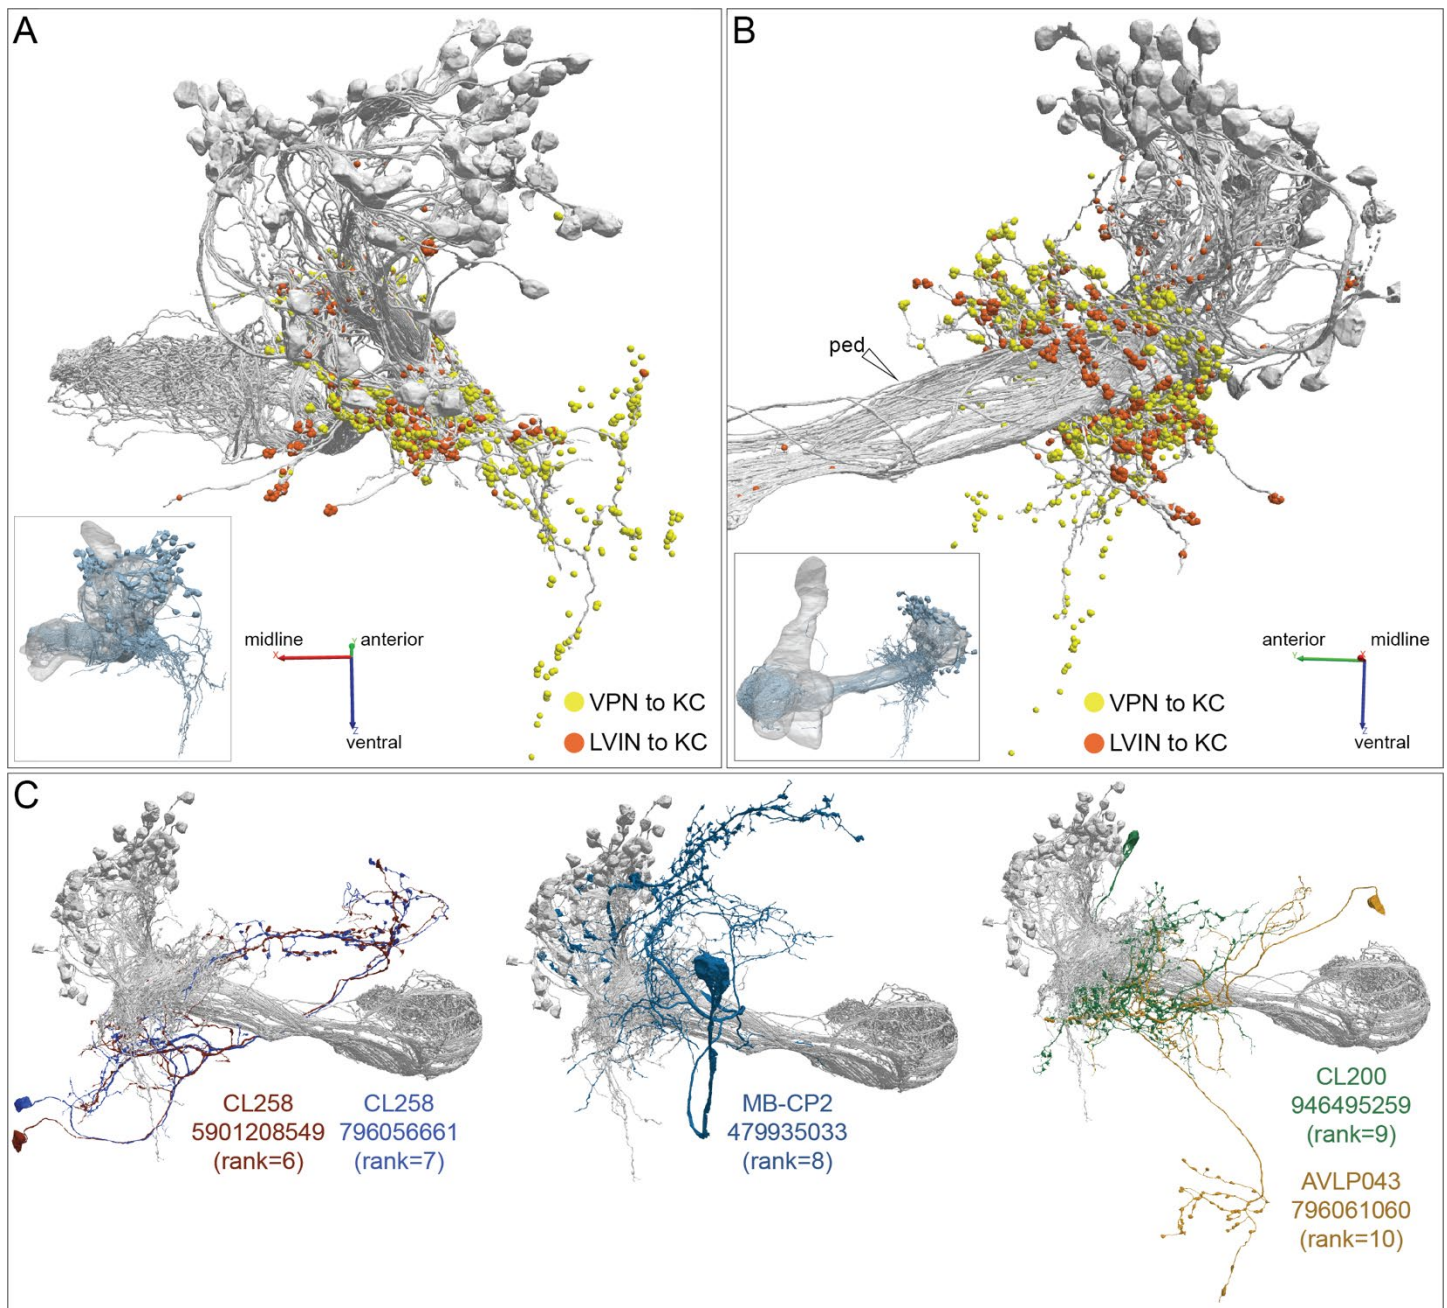

Figure 10-figure supplement 4. Additional views of the morphologies of VPN and LVIN inputs to the vACA.

(A-B) Additional views of the distribution of VPN and LVIN inputs onto γ_d and γ_{s1} KCs (grey); synapses are color-coded as indicated. The insets show the orientation of the view shown. Note the spatial segregation of these two types of connections. VPNs onto KC_{yd} dendrites in an area ventral to the CA, previously recognized as the vACA (Butcher et al., 2012), as well as in a diffuse ring surrounding the base of the CA; synapses from LVINs are restricted to the ring. An additional view is shown in Figure 10B. (C) The morphologies of the LVINs ranked sixth to tenth in conveying the highest visual input to the vACA are shown; KCs are in grey. The orientation of the images is the same as the inset shown in Figure 10B.

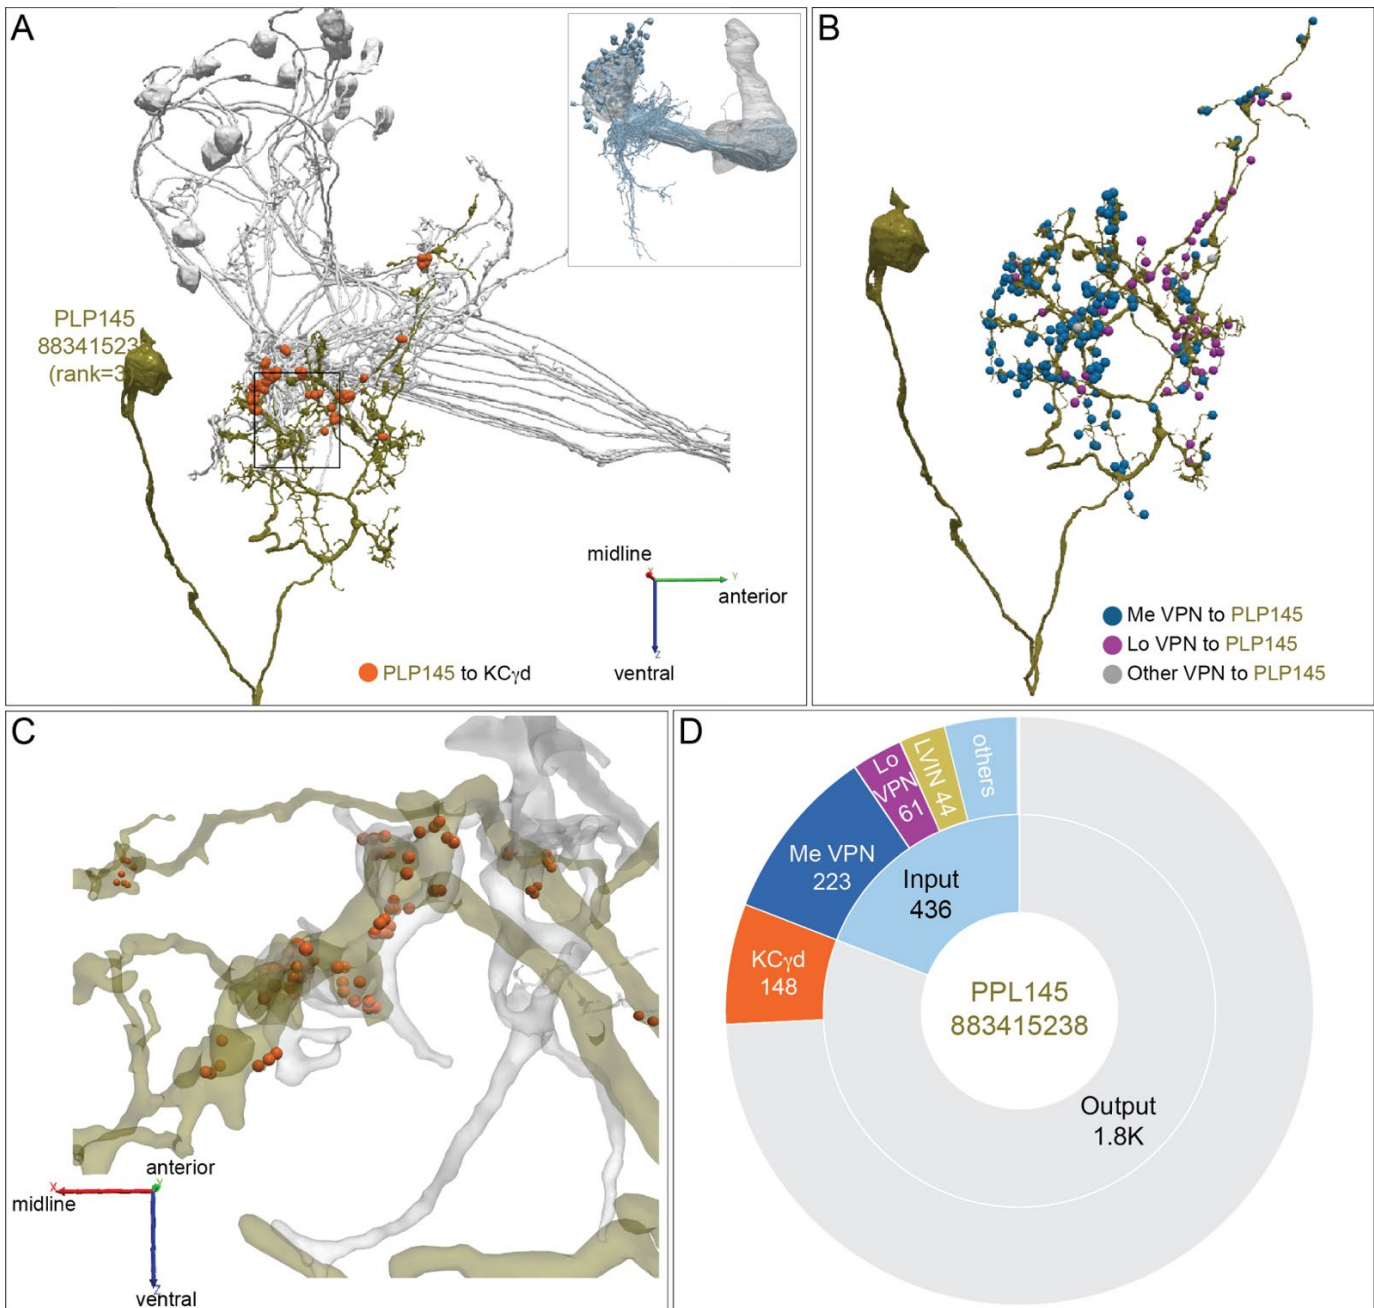

Figure 10-figure supplement 5. Distribution of VPN inputs onto an LVIN .

(A) The LVIN [PLP145](#) (883415238; green) that conveys the third highest amount of visual input to the vACA is shown along with the positions where it makes synaptic output (orange dots) onto a subset of γ d KCs (grey). The inset shows the orientation of the MB in this image. (B) PLP145 receives synaptic input from three classes of VPNs: ME, LO, other, shown color-coded. Other VPNs include cells that could not be placed into the ME or LO groups based on their arbors in the hemibrain volume or that appear to have dendrites in both ME and LO. (C) Enlarged and rotated view of the boxed area in (A). Note that synaptic connections from PLP145 to γ d KCs lack the claw-like structure typical of olfactory PN to KC connections in the CA. (D) Pie chart showing the portion of the total input to PLP145 (light blue) that comes from direct ME (dark blue) and LO VPNs (purple), other LVINs (yellow) and other neurons (blue); the portion of PLP145's total output (grey) that goes to KC γ (orange) is also shown.

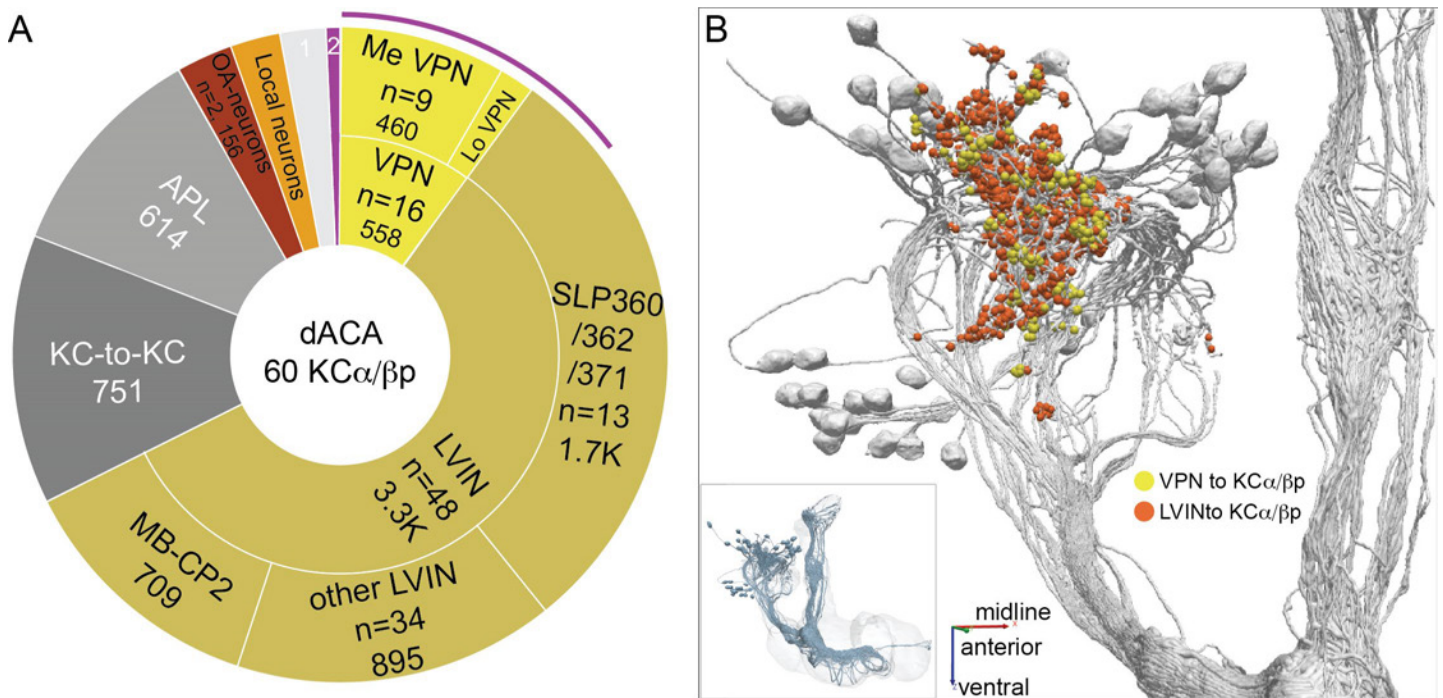

Figure 11. Dorsal accessory calyx (dACA).

The dendrites of the 60 α/β KCs define the dACA. The pie chart shows a breakdown of the inputs to these KCs. The majority convey visual information, either directly from visual projection neurons (VPN; 9.8%) or through intermediate local visual interneurons (LVIN; 57.8%) that receive input from VPNs (see Figure 11-figure supplement 1). VPNs can be subdivided based on the location of their dendrites in either ME or LO, as indicated in the outer circle. More than two-thirds of the indirect input is mediated by the LVIN cell types [SLP360](#), [SLP362](#), and [SLP371](#), shown in Figure 11-figure supplement 1C; this SLP360/361/371 cluster of 13 neurons contributes about 30% of total input to the 60 α/β KCs in the dACA. Neurons of similar morphology have also been observed to be presynaptic to KC α/β in the dACA in a recent study (Li et al., 2020). Another LVIN, [MB-CP2](#) (LHPV3c1) (479935033), provides 12.6% of the input to KCs in the dACA; however, only a small percentage of its inputs are visual (see Figure 11-figure supplement 1A and E). The total visual information presented to KCs by VPNs and LVINs is indicated by the purple arc around the outer layer; it reflects the direct input from the VPNs plus the fraction of the LVIN input that represents visual input. The next most prominent inputs are KC-to-KC synapses in the dACA (13.3%), from APL (10.9%), from two octopaminergic neurons (2.8%; [OA-VPM3](#), see Figure 3-figure supplement 1D, and [OA-VUMa2](#), see Figure 3-figure supplement 1F); and [local interneurons](#) (n=22; 2.3%). Remaining input, “others”, are input from 102 different neurons that are all weakly connected; and numbered sector 1 are mPNs (0.7%). The dendrites of KC α/β neurons in the dACA (Tanaka et al., 2008; Zhu et al., 2003) are reportedly activated by bitter or sweet tastants (Kirkhart and Scott, 2015). However, the KC α/β are not required for taste conditioning, which instead appears to depend on γ KCs (Kirkhart and Scott, 2015) and we were unable to identify strong candidates for delivering gustatory sensory information to the dACA. The PN VP5+Z adPN ([5813063239](#)) connects to two α/β KCs has dendrites in the SEZ (Figure 9-figure supplement 3). But this is the only gustatory PN we can associate with the dACA, and it primarily projects to KC γ m neurons through which it might participate in conditioned taste aversion (Kirkhart and Scott, 2015). (B) Color-coded synaptic connections from visual projection neurons (VPN; yellow) and local visual interneurons (LVIN; orange) onto α/β KCs (grey). Note that, unlike in the vACA, there are more connections from LVINs than VPNs in the dACA.

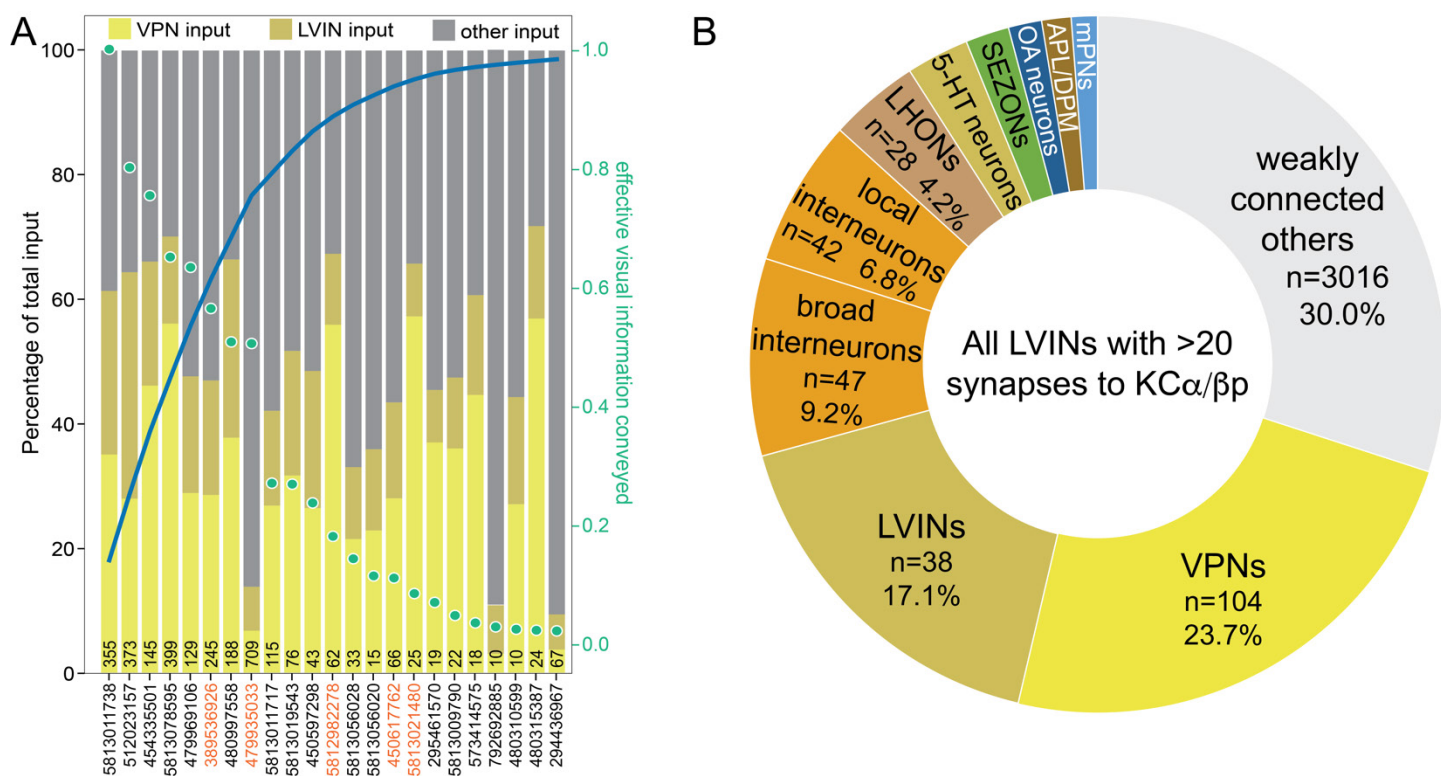

Figure 11-figure supplement 1. VPN and LVIN inputs to the dACA.

(A) Plot of interneurons carrying visual information to the α/β KCs ranked by the strength of their effective contribution of visual information. For a given interneuron, this quantity is computed by multiplying the number of synapses that interneuron makes onto α/β KCs by the fraction of its input synapses that come from visual projection neurons. The green dots show this effective visual information quantity. Values are normalized to the most strongly connected LVIN, which was assigned a value of 1.0 (green scale on the right side of the plot). The blue line shows the cumulative amount of effective visual information conveyed by LVINs; over 80% of the input is delivered by the top ten LVINs. The color-coded bars indicate the percentage of that neuron's input that comes from VPNs, LVINs, and other neurons. The black number at the base of each bar shows the number of synapses made by that LVIN to KCs in the dACA. The LVINs whose ID numbers are shown in orange also provide input to the γ d KCs in the vACA. Links to these 10 LVINs in neuPrint are as follows: [SLP371](#), [SLP360](#), [CL357](#), [SLP362](#), and [MB-CP \(LHPV3c1\)](#). Note that many of lower ranked LVINs that receive high levels of VPN input do not make strong connections to KCs and are therefore presumably performing some other role in integrating visual information. (B) Multiple sensory pathways contribute to the LVINs that connect to α/β KCs. Effective input delivered by local neurons that each of the 19 LVINs that make at least a total of 20 synapses to α/β KCs are shown, all of which are LVINs except one OA-neuron ([329566174](#)) which makes weak connections to most $\text{KC}\alpha/\beta$ (50 of 60 total α/β KCs). We did not find other interneurons strongly connected to the vACA KCs that were not LVINs; that is, interneurons that did not also receive VPN input. Effective input is calculated by multiplying the indicated neuronal population's synaptic input to each of the 19 LVINs times the fraction of the α/β KCs' total input coming from that LVIN, and then summing across all 19 LVINs. Effective input is expressed as the percentage of the total input from these 19 LVINs to α/β KCs that originated with the indicated neuronal population. The number of individual cells in each population is also indicated. Seventy percent of the most strongly connected upstream neurons (total of 350) to the 19 LVINs have been classified. The strongest inputs are VPNs and LVINs contributing combined 40.8% effective input. Local (those confined to the neuropil that is adjacent to dACA) and broad (those that expand through multiple neuropils) interneurons contribute a total of 16.0% of the effective input. Other prominent inputs are [LHONs](#), [5-HT neurons](#) (n=2, 2.9%), [SEZONs](#) (n=7, 2.0%), [OA-neurons](#) (n=3, 1.5%), APL and DMP (1.4%) and [mPNs](#) (n=5, 1.2%).

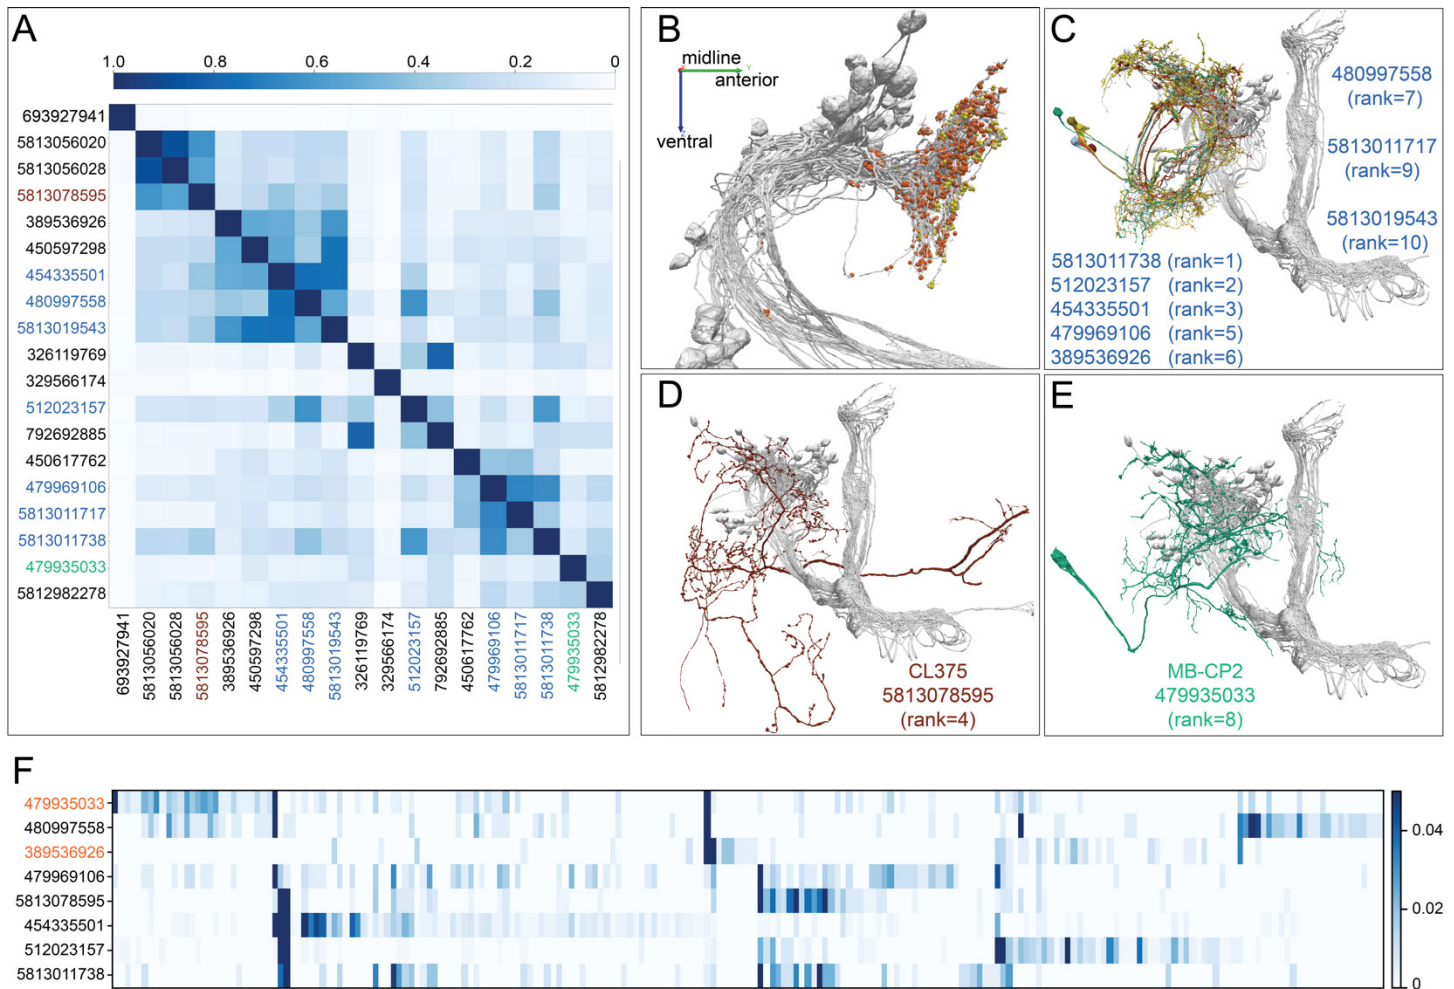

Figure 11-figure supplement 2. LVINs that convey visual input onto α/β KCs.

(A) A plot showing the cosine similarity of inputs to each of the 19 LVINs that provide more than 20 synapses to α/β KCs described in Figure 11-figure supplement 1B. (B) An additional view of the distribution of VPN and LVIN inputs onto α/β KCs. Note that LVIN input locations tend to be more posterior than those of VPNs. (C) Of the top ten LVINs based on visual input delivered to α/β KCs, eight are neurons with similar morphologies that fall into three cell types, SLP360, SLP363 and SLP371, shown here. (D) The LVIN conveying the fourth highest visual input to the vACA. (E) MB-CP2, the LVIN conveying the eighth highest visual input to the vACA; MB-CP2 (LHPV3c1) also provides 1% of input to KCs in the CA (see Figure 9). (F) A plot showing the similarity of VPN inputs for each of the top ten LVINs (using the ranking from panel A). Each vertical blue bar represents a different VPN and the intensity of the color reflects the percentage of the corresponding LVIN's total VPN input that is contributed by that VPN. The order of the VPNs and LVINs was determined using spectral clustering.

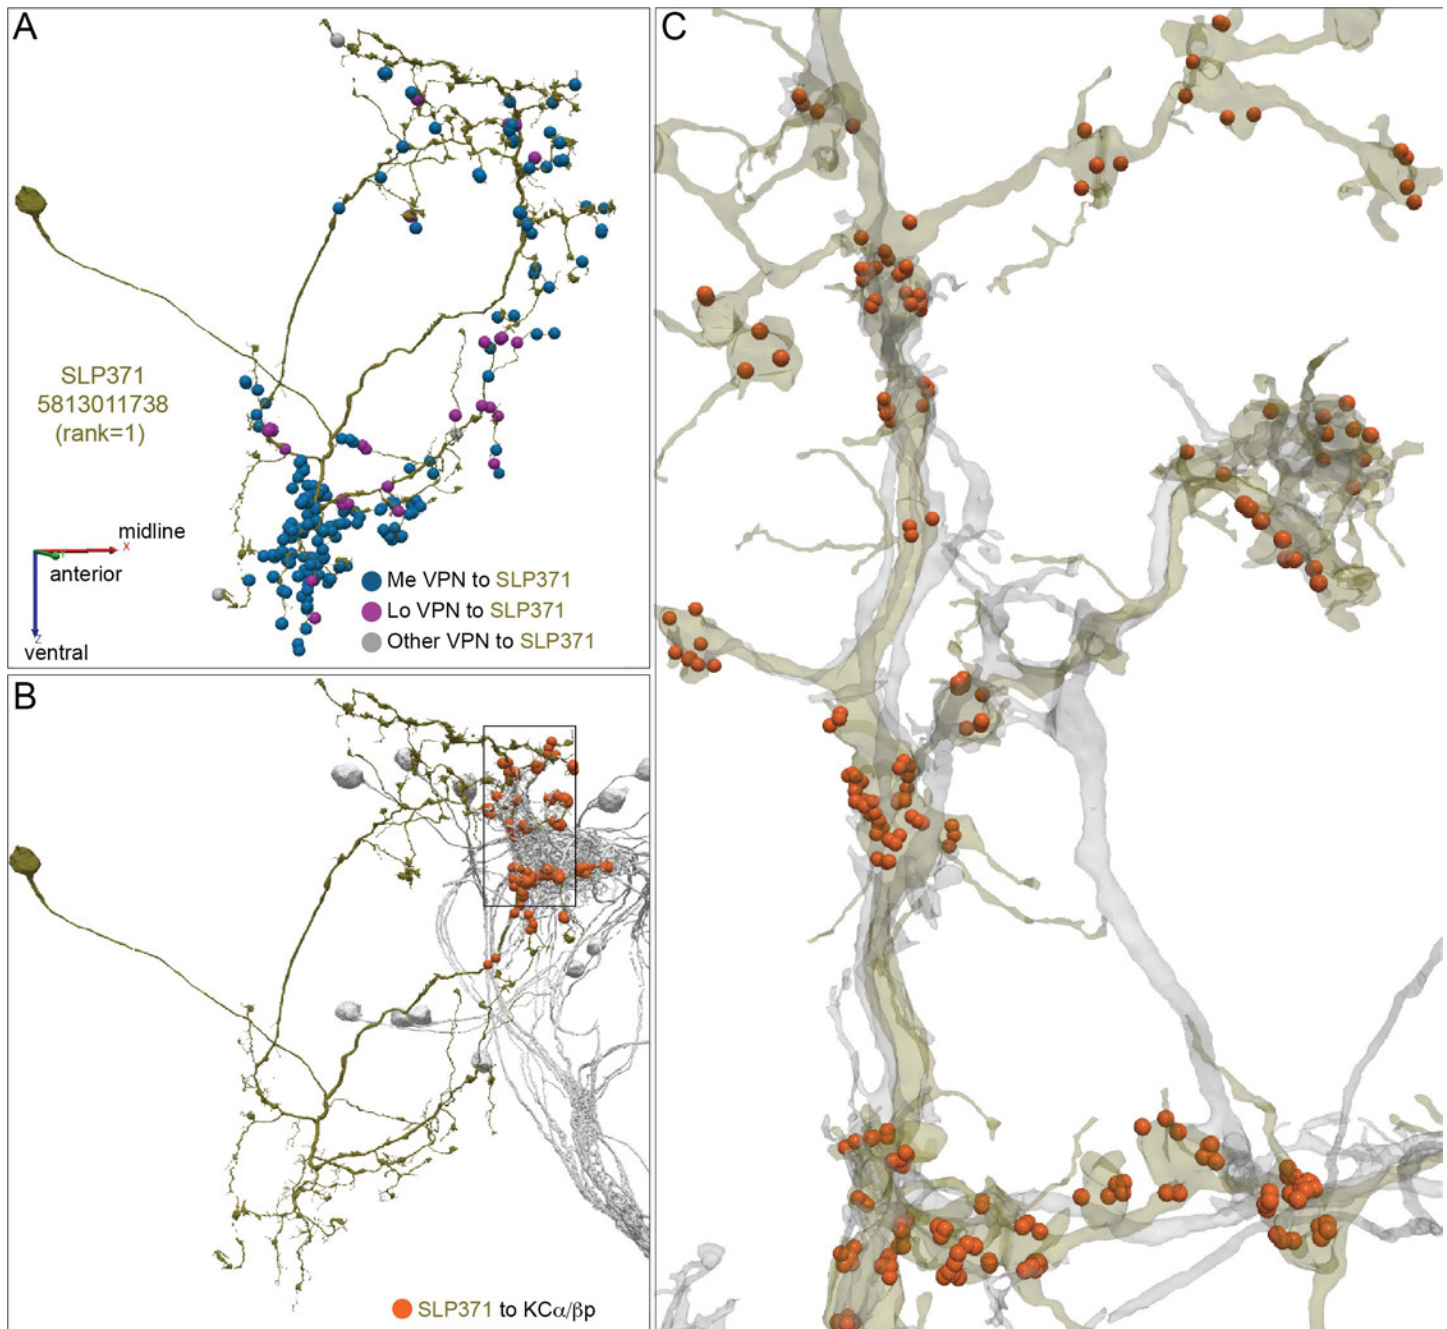

Figure 11-figure supplement 3. Detailed morphology of a dACA LVIN.

(A) One of the two SLP371 neurons (5813011738; green) is shown with the positions of its synaptic input from three color-coded classes of VPNs. (B) Synapses from this LVIN (green) onto the subset of α/β KCs (grey) that it contacts are shown as orange dots. (C) Enlarged and rotated view of the box in (B). Note that connections from the LVIN to α/β KCs lack the claw-like structure typical of the synapses between olfactory projection neurons and KCs in the CA.

Figure 11-figure supplement 4. Similarity of VPN inputs to individual LVINs that innervate the vACA or the dACA. A heatmap showing the similarity of LVIN inputs from VPNs. It reveals the degree of diversity of the VPN inputs received by LVINs, as well as the existence of clusters of LVINs that receive similar inputs. Each square in the heat map represents a cosine similarity of the VPN inputs to a pair of LVINs. The ordering of the LVINs shown was determined by clustering based on their inputs. Colors on the diagonals indicate whether the given LVIN is among the top 20 inputs to the vACA (green), to the dACA (pink), to both the vACA and dACA (orange), or neither (dark blue).

Figure 11-figure supplement 5. Similarity of non-visual inputs to individual LVINs.

A heatmap in the same format as Figure 11-figure supplement 4 but showing the similarity of LVIN inputs from non-visual (i.e. non-VPN, non-LVIN) neurons. LVINs are shown in the same order as in Figure 11-figure supplement 4. The fact that substantial structure is preserved between these plots indicates that clusters of LVINs with similar visual inputs also tend to receive similar inputs from neurons that do not (directly) relay visual information. Colors on the diagonals indicate whether the given LVIN is among the top 20 inputs to the vACA (green), to the dACA (pink), to both the vACA and dACA (orange), or neither (dark blue).

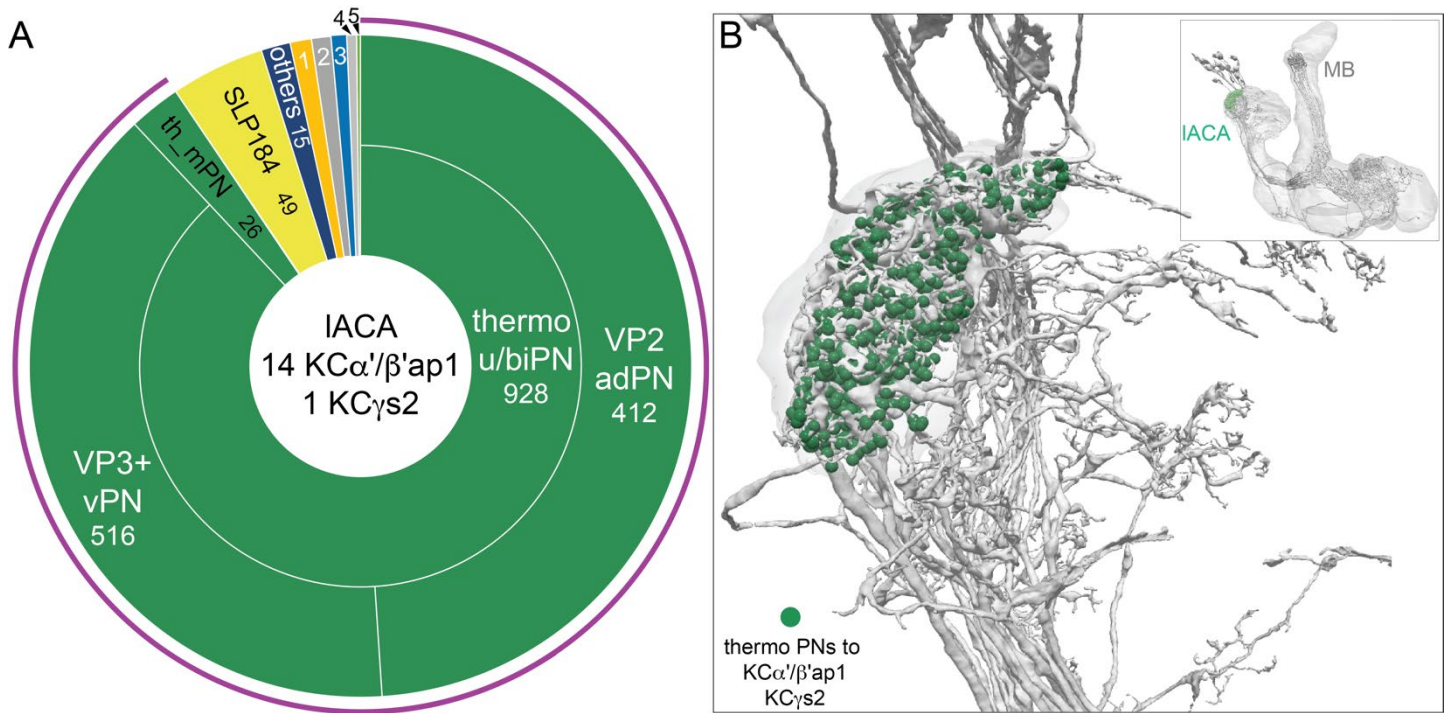

Figure 12. Lateral accessory calyx (IACA).

The IACA is defined by the limits of the presynaptic boutons of [VP2 adPN](#) (1975878958) and [VP3+ vPN](#) (663432544); there also appear to be glia separating the IACA from main CA. Fourteen α'/β' ap1 KCs and the γ s2 KC innervate the IACA. (A) A pie chart showing inputs to the 15 IACA-innervating KCs. The majority of input to these KCs is from the two thermosensory uPNs, VP2 adPN and VP3+ vPN, that contribute 928 synapses, of which the single γ s2 KC receives 268. Other prominent inputs are one local interneuron ([SLP184](#)) and two thermo/hygrosensory mPNs. Eight interneurons (other) contribute 15 synapses. Sources of input indicated by the other numbered sectors are as follows: 1, circadian clock-associated neurons (1.0%); 2, APL (0.9%); 3, MB-C1 (0.7%); 4, KC-to-KC connections and 5, other PNs (0.2%). The total temperature information presented to KCs by PNs is indicated by the purple arc around the outer layer. Note that KCs in IACA have dramatically less KC-to-KC and APL input than those in the dACA and the vACA. (B) Synaptic connections from thermo uPNs (green) to KCs (grey). The inset shows the orientation of the MB.

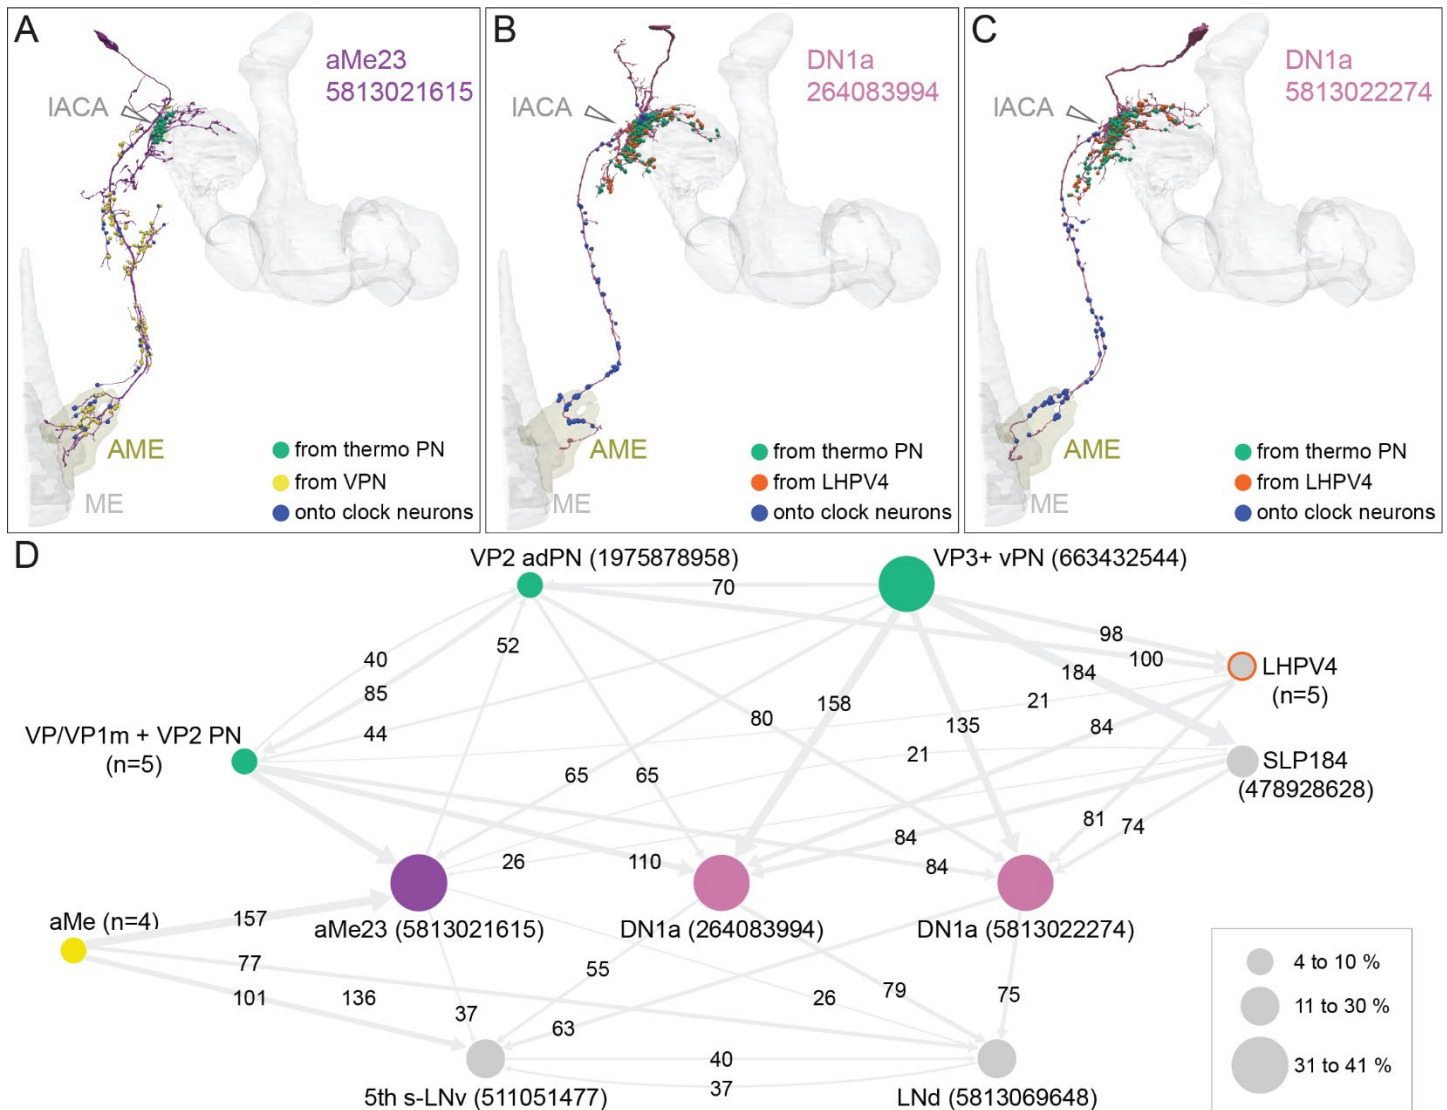

Figure 12-figure supplement 1. DN1a neurons relay temperature cues from the IACA to the circadian clock.

(A) Morphology of a DN1a-like neuron ([aMe23](#)) with the positions where it receives thermosensory input in the IACA (green) and visual inputs (yellow) in the accessory medulla (AME) and the PLP. The position of its synapses onto two clock neurons, the 5th s-LNv and one LNd, are shown in blue. (B-C) Morphologies of [two DN1a neurons](#) with inputs from thermosensory PNs and the [LHPV4](#) interneuron, as well as outputs to the same two clock neurons 5th s-LNv and LNd, shown color-coded. (D). Simplified circuit diagram. The [aMe23](#) and DN1a neurons show different patterns of input from visual projection neurons ([aMe](#); yellow), thermosensory and hygrosensory projection neurons ([VP/VP1m + VP2 PN](#), [VP3+ vPN](#), [VP2 adPN](#); green), and interneurons (LHPV4; grey with red outline) (Marin et al., 2020). Temperature entrainment of the circadian clock requires input from the arista (Yadlapalli et al., 2018; Alpert et al., 2020), which house the VP3 and VP2 sensory neurons (Gallio et al., 2011); the connections we observed provide a potential anatomical substrate for arista-dependent temperature entrainment of the clock. DN1a (Helfrich-Förster, 2004; Shafer et al., 2006) and aMe23 neurons provide input to the circadian clock neurons 5th s-LNv and LNd. Connections of fewer than 20 synapses have been omitted. The sizes of the three green circles representing PN types indicate the percentage of those neurons' total output (based on synapse number) going directly to other neurons in the diagram; the sizes of the circles representing all other neurons indicate what percent of that neuron's total input comes directly from other neurons in the diagram.

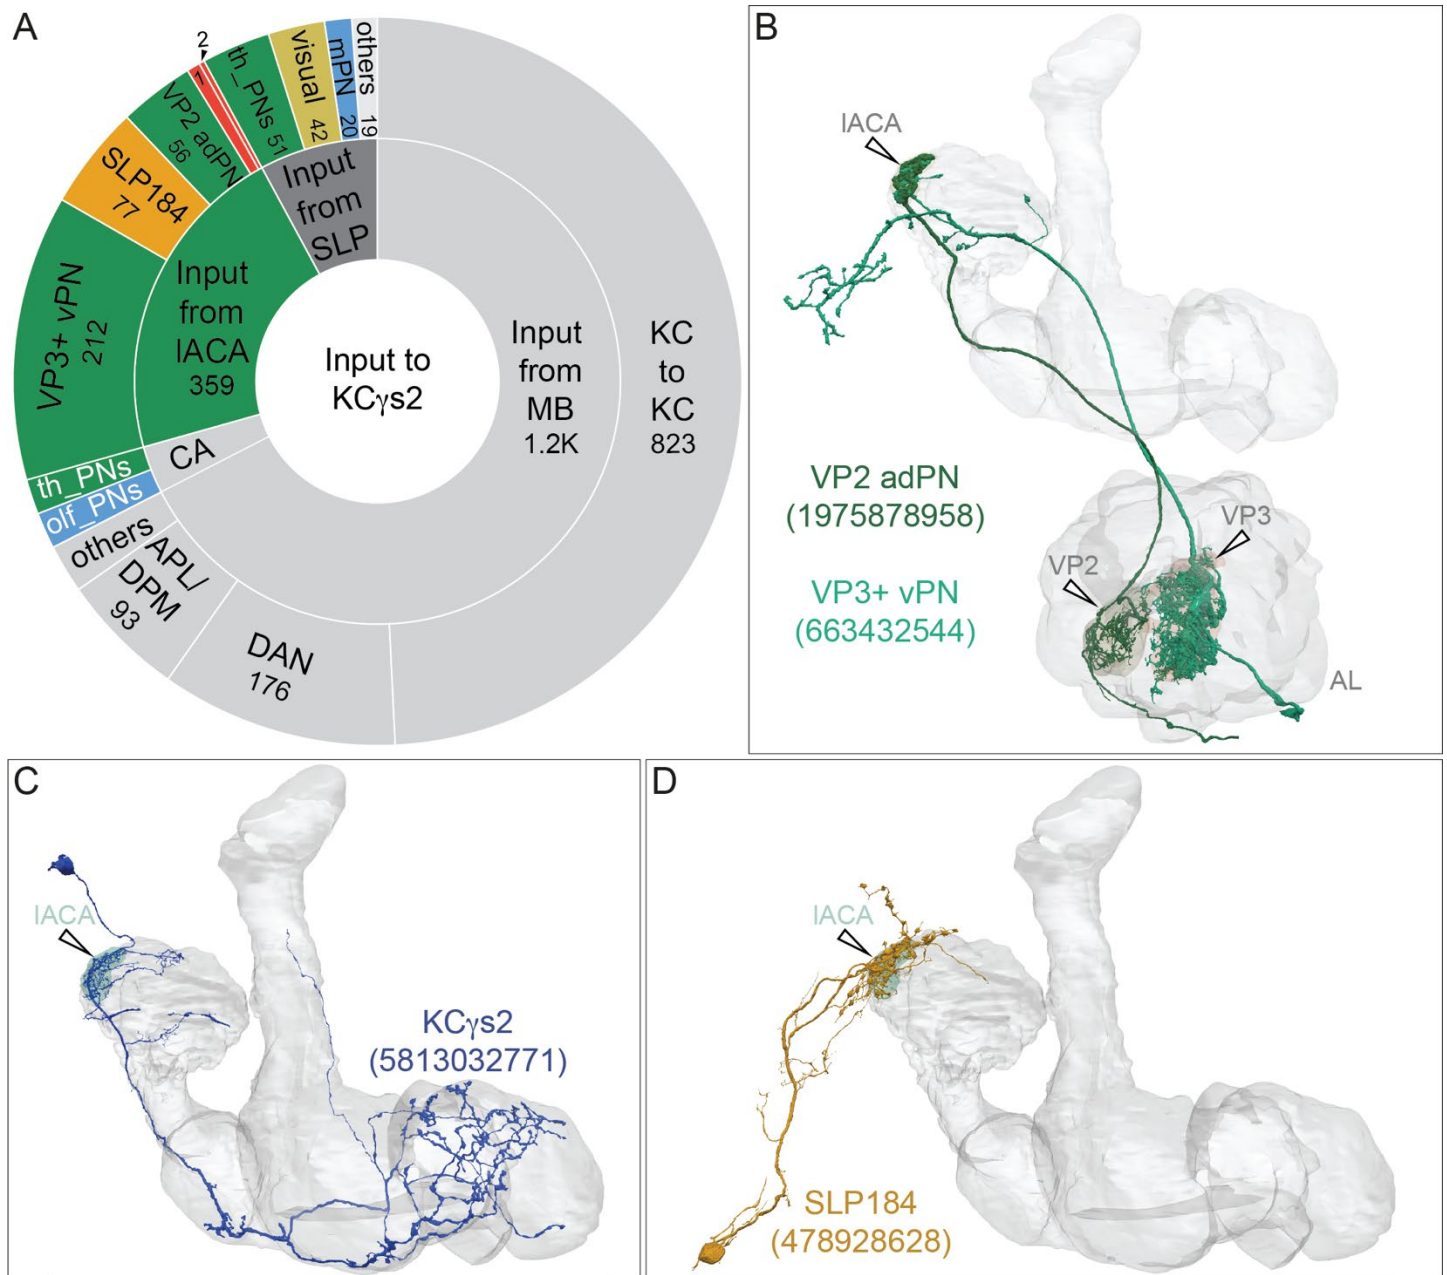

Figure 12-figure supplement 2. KC γ s2 and its inputs.

(A) Distribution of inputs to [KC \$\gamma\$ s2](#). KC γ s2 receives the vast majority of its sensory input in the IACA from thermo/hygrosensory PNs, but also receives a small amount of visual and olfactory information. Note that the pie chart reflects all of KC γ s2's inputs, not just those that occur in the IACA. KC γ s2 receives nearly half its input from putative KC-to-KC synapses in the γ lobe. The γ s2 KC receives the majority of its sensory input in the IACA from two thermal PNs (VP3+ vPN and VP2 adPN); other IACA inputs include the interneuron [SLP184](#) (77, 4.5%) and neurons represented by the numbered sectors: 1, aMe23 (10, 0.7%) and 2, VP1m+VP2_lvPN2 (8, 0.5%). The γ s2 KC also receives 132 synapses (7.7% of its input) from its arbor that lies in the SLP, outside main CA and IACA, indicated in the grey wedge, as well as a small amount of input from other thermal and olfactory PNs in the CA. (B) Morphologies of thermosensory PNs VP2 adPN and VP3+ vPN, which are the major inputs to the IACA, are shown. (C) Morphology of KC γ s2. (D) Morphology of the interneuron SLP184.

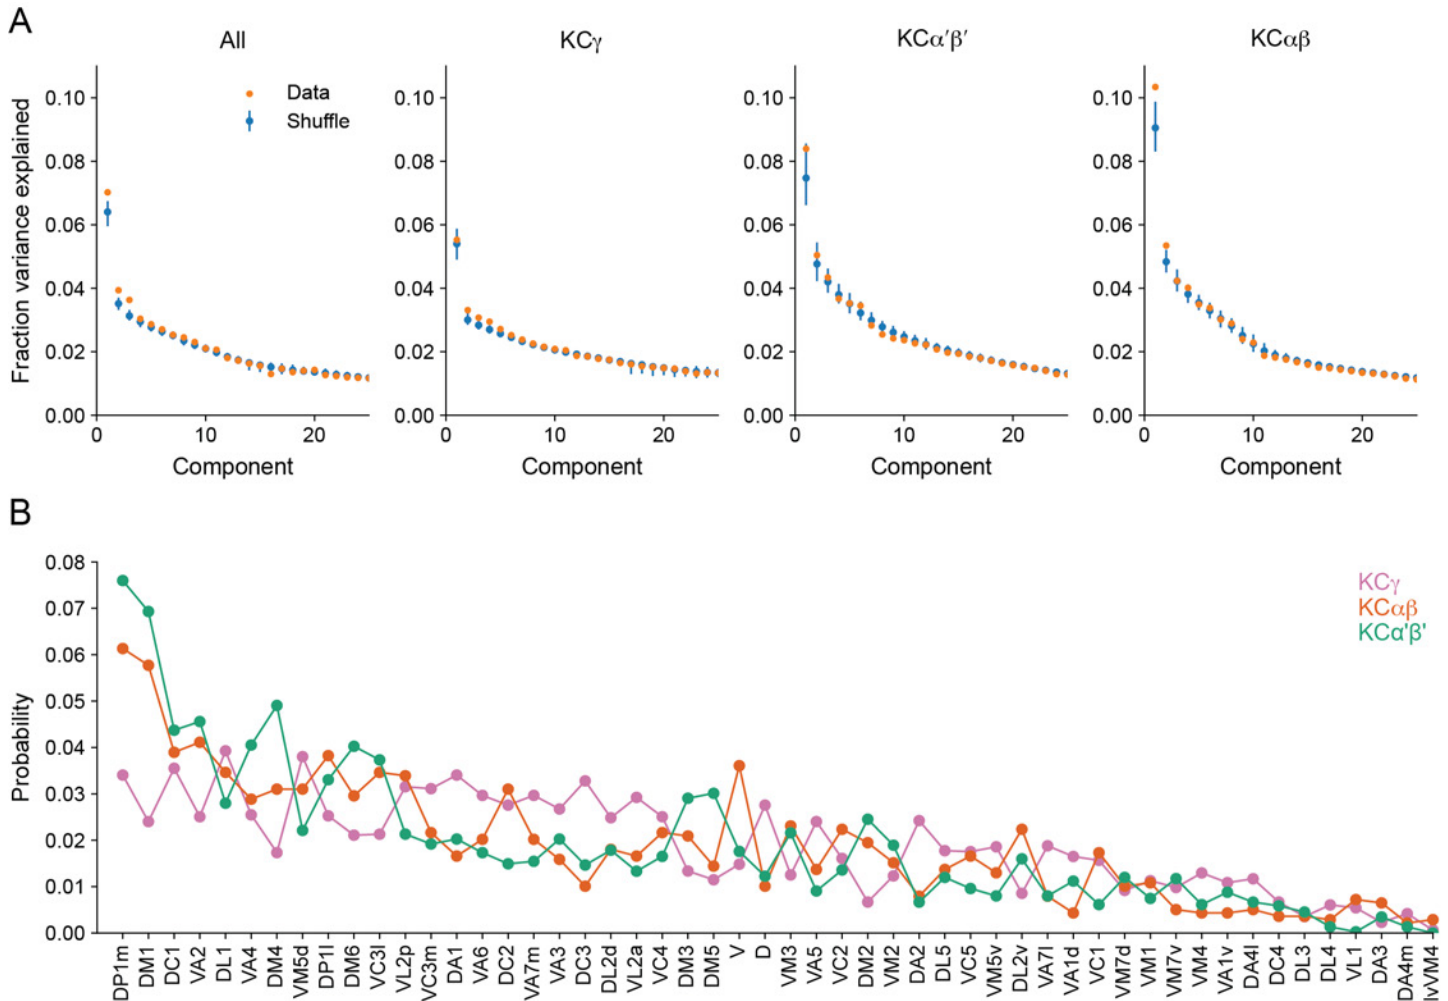

Figure 13. Comparison of KC input connectivity to random models.

(A) Fraction of variance explained by components identified via principal components analysis of the olfactory uPN to KC input connectivity matrix—a binary matrix containing ones and zeros for present or absent connections between KCs and their inputs, at a threshold of 5 synapses. Results are shown for the reconstructed data (orange) and for a collection of shuffled models (blue) in which each KC retains the same total number of connections but samples among all uPNs randomly, with a probability proportional to the total number of connections each uPN makes. Such models therefore retain the degree distribution across KCs, (that is, the probability distribution of the number of claws formed by individual KCs) and the average connection probability for each uPN, but no other structure. Bars indicate 95% confidence intervals for shuffled models. Deviations in the first few components indicate structure inconsistent with a random model.

Left: All KCs; Right: Analysis restricted to the indicated KC subtypes (visual α/β and γ d KCs, as well as γ s KCs, were excluded). (B) Probability of uPN-to-KC connections from each olfactory glomerulus, sorted by most to least well-connected. Probabilities are plotted separately for the KC subtypes shown in (A).

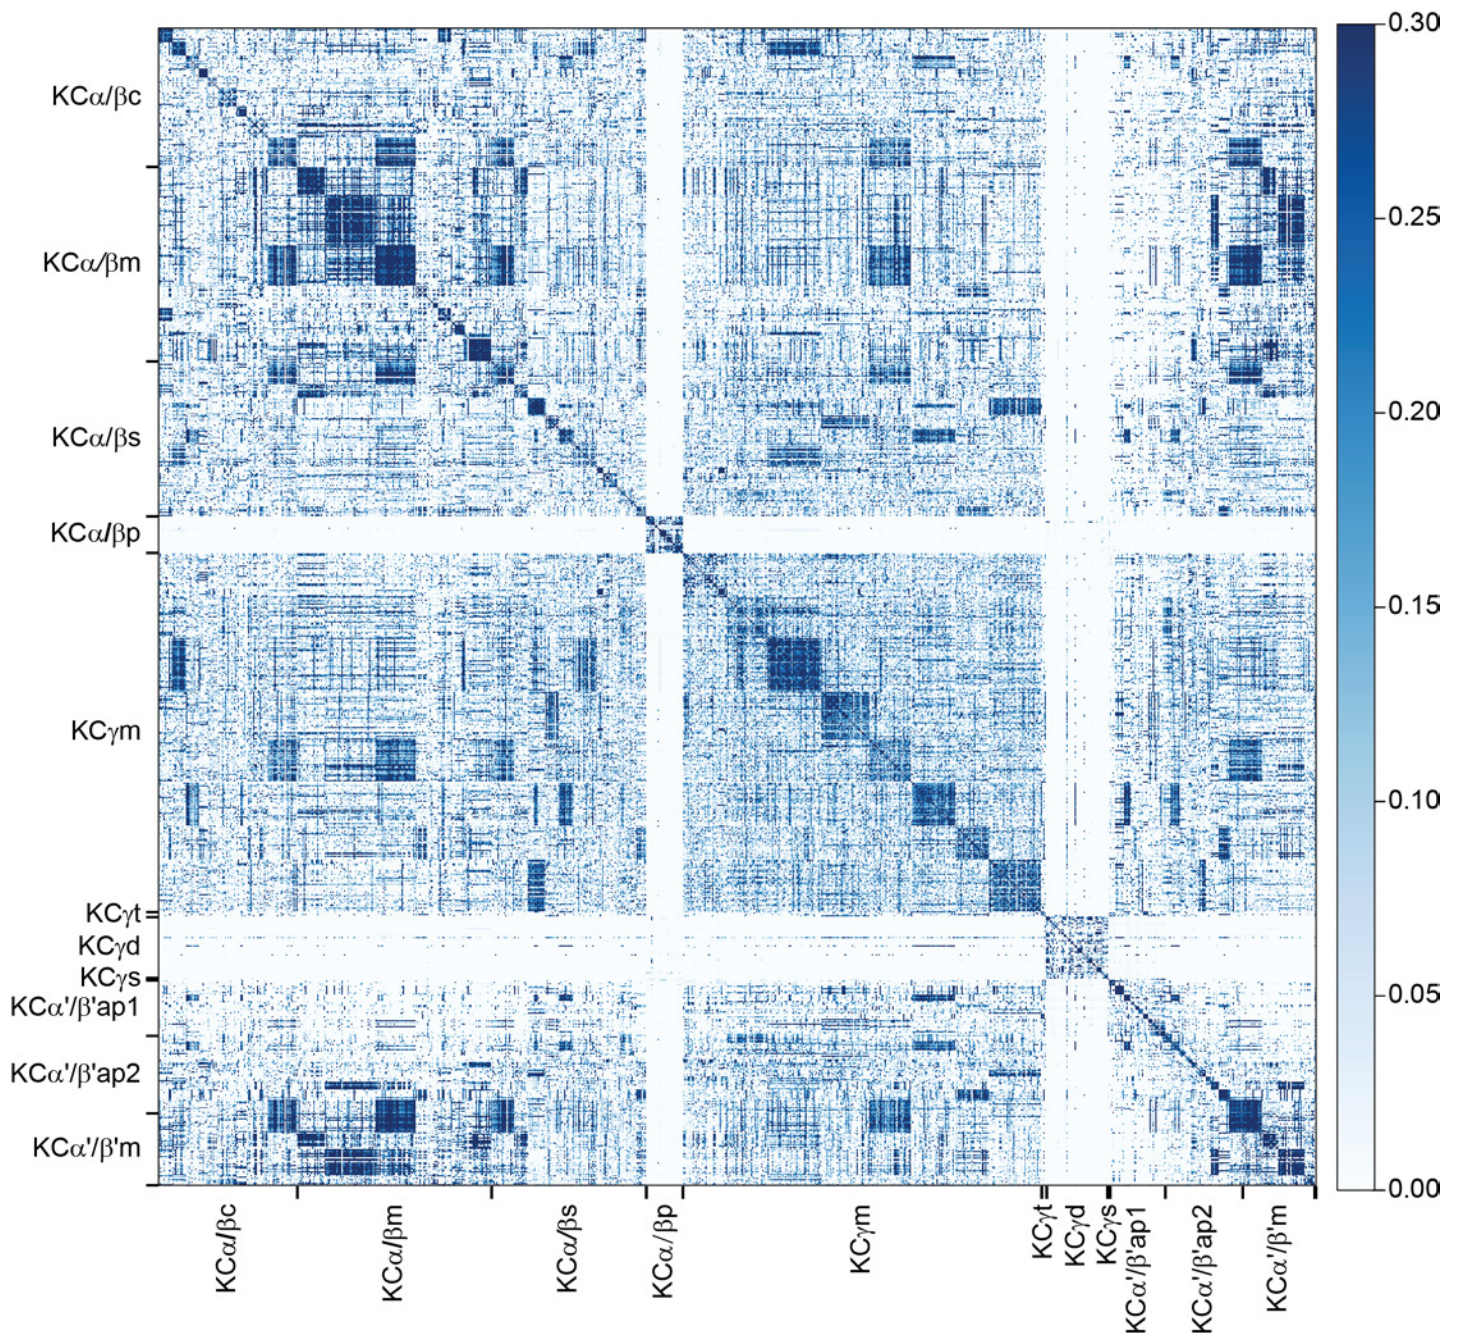

Figure 13-figure supplement 1. Clustering KCs based on the similarity of their inputs from PNs.

Cosine similarity of PN inputs to KCs. This metric measures the degree of overlap in the PN inputs, weighted by synapse count, to each pair of KCs. Each PN is treated individually, rather than being grouped by cell type. KCs are grouped by subtype, and then the ordering within each subtype is determined by spectral clustering. The optimal number of clusters within each type is determined using the silhouette score and capped at 10. The potential computational significance of groups of KCs responsible for distinct PN inputs is modeled in Figure 37.

Figure 13-figure supplement 2. Similarity of KC outputs to MBONs.

Cosine similarity of KCs outputs to MBONs. KCs are grouped by subtype, and then indexed in the same order as in Figure 13.

Figure 14. Effect of spatial organization on the KC representation.

(A) Histogram of pairwise distances between boutons formed by PNs from the same glomerulus (top) or different glomeruli (bottom). (B) Average number of nearby boutons within a given radius of each PN bouton. (C) Illustration of shuffling procedure used to randomize PN-to-KC connectivity within a given radius. Small dots: synapses formed by each PN onto KCs. Large dots: Centroid location of identified boutons. Claws are randomly reassigned (red arrows) to boutons whose centroids lie within the given radius, indicated by the dotted grey line. (D) Participation ratio (top) and dimension (bottom) of models constructed by shuffling connectivity within a specific radius. The dependence of these two quantities on the shuffle radius shows a modest effect of the spatial organization of the CA on the KC representation in the model.

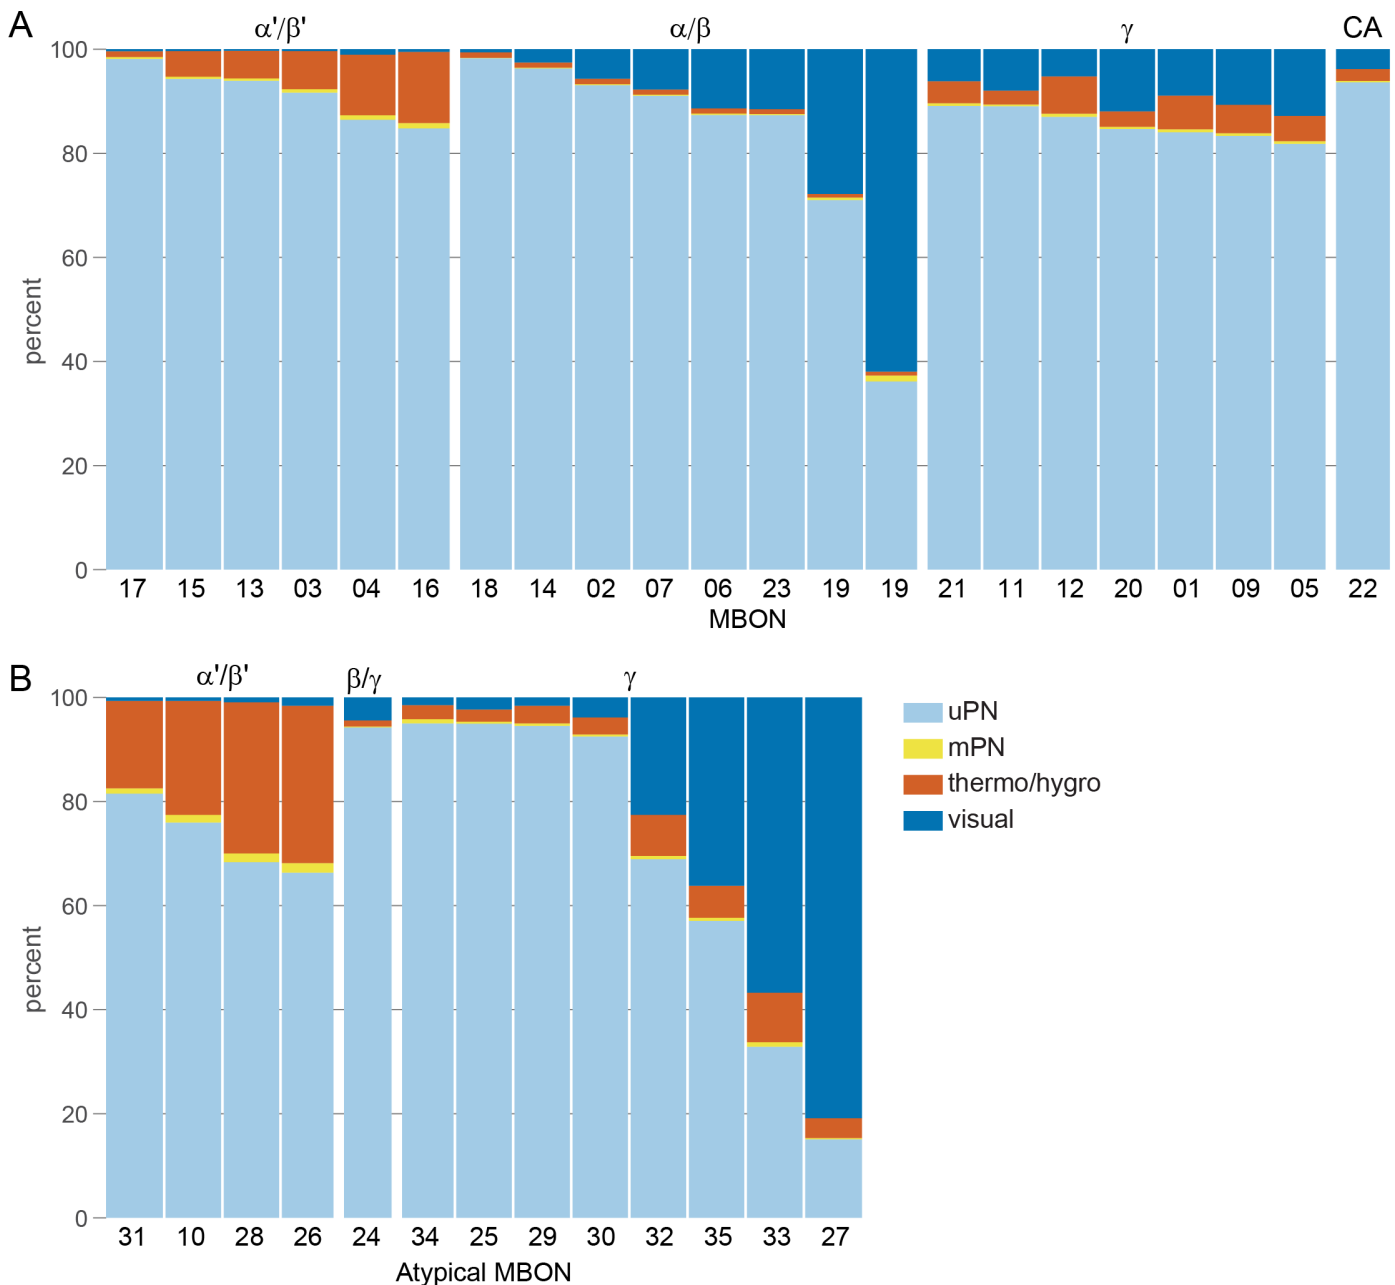

Figure 15. Structure in PN-KC-MBON connectivity.

(A) Effective PN to MBON connectivity. MBONs within the α'/β' lobe receive input primarily from uniglomerular olfactory PNs (uPNs), but they also show a gradation of input from thermo-hygro-sensory PNs. MBONs from the α/β lobes show a similar, although stronger, variation in the amount of input they receive from visual PNs. MBONs from the γ lobe are more uniformly innervated. For cases where the MBON cell type contains more than one cell, results from the individual cells have been averaged in this figure, with the exception of the two MBON19 ($\alpha 2p3p$ s); both MBON19s are specialized for visual input, but to different extents. (B) Effective PN to atypical MBON connectivity. The gradation in non-olfactory input is stronger than for typical MBONs. In particular, the majority of the input to MBON33 ($\gamma 2\gamma 3$) and MBON27 ($\gamma 5d$) is visual. In this figure and its supplements, the MBONs have been grouped by the MB lobe they primarily innervate and then ordered, within these groups, according to their selectivity. MBON24 ($\beta 2\gamma 5$) receives input from both the β and γ lobes. Percentages indicate the amount of input to each MBON from a particular PN type divided by the total sensory input to that MBON.

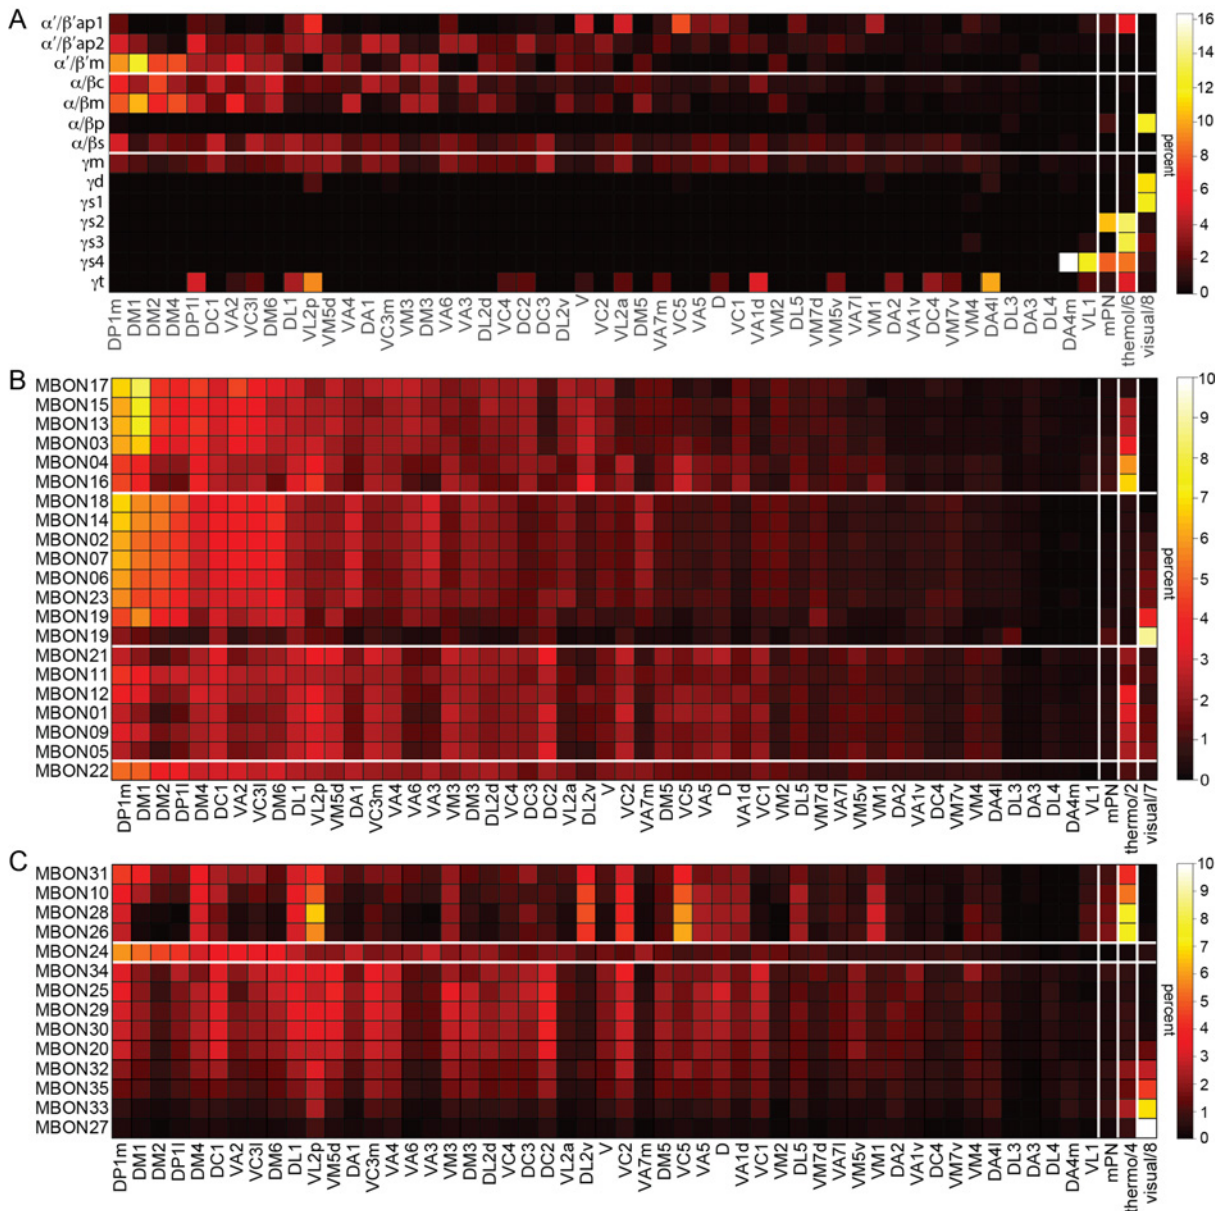

Figure 15-figure supplement 1. PN connections to KC types and effective PN to MBON connectivity.

Detailed views of the PN inputs to KCs and MBONs. The uPN types are listed individually. Inputs from multiglomerular PNs (mPN), thermo/hygro-sensory (thermo) and visual pathways have been pooled over all input neurons of each type. Percentages indicate the amount of effective input due to a particular PN type divided by the total sensory input to each target cell or population; the thermo-hygro-sensory and visual results have been divided by the factors indicated in each column, to keep the color scale within reasonable bounds. (A) Inputs from uPNs, mPNs, thermo/hygro-sensory and visual pathways to KCs of different subtypes. (B) Inputs from uPNs, mPNs, thermo/hygro-sensory and visual pathways to each typical MBON. (C) The same plot as in (B), but for the atypical MBONs. Note that this plot reflects only input that atypical MBONs receive from KCs and ignores other input that they receive from their dendrites that extend outside the MB lobes. Approximately 80 and 55 percent of the inputs to MBON27 (γ 5d) and MBON33 (γ 2-3), respectively, convey visual information (see Figure 15B). Note that input from VC5 and VL2p is highly represented by the same MBONs that receive strong input from thermo-hygro-sensory PNs, supporting the idea that these glomeruli may also convey thermo-hygro-sensory information (Hamada et al., 2008; Frank et al., 2015; Marin et al., 2020).

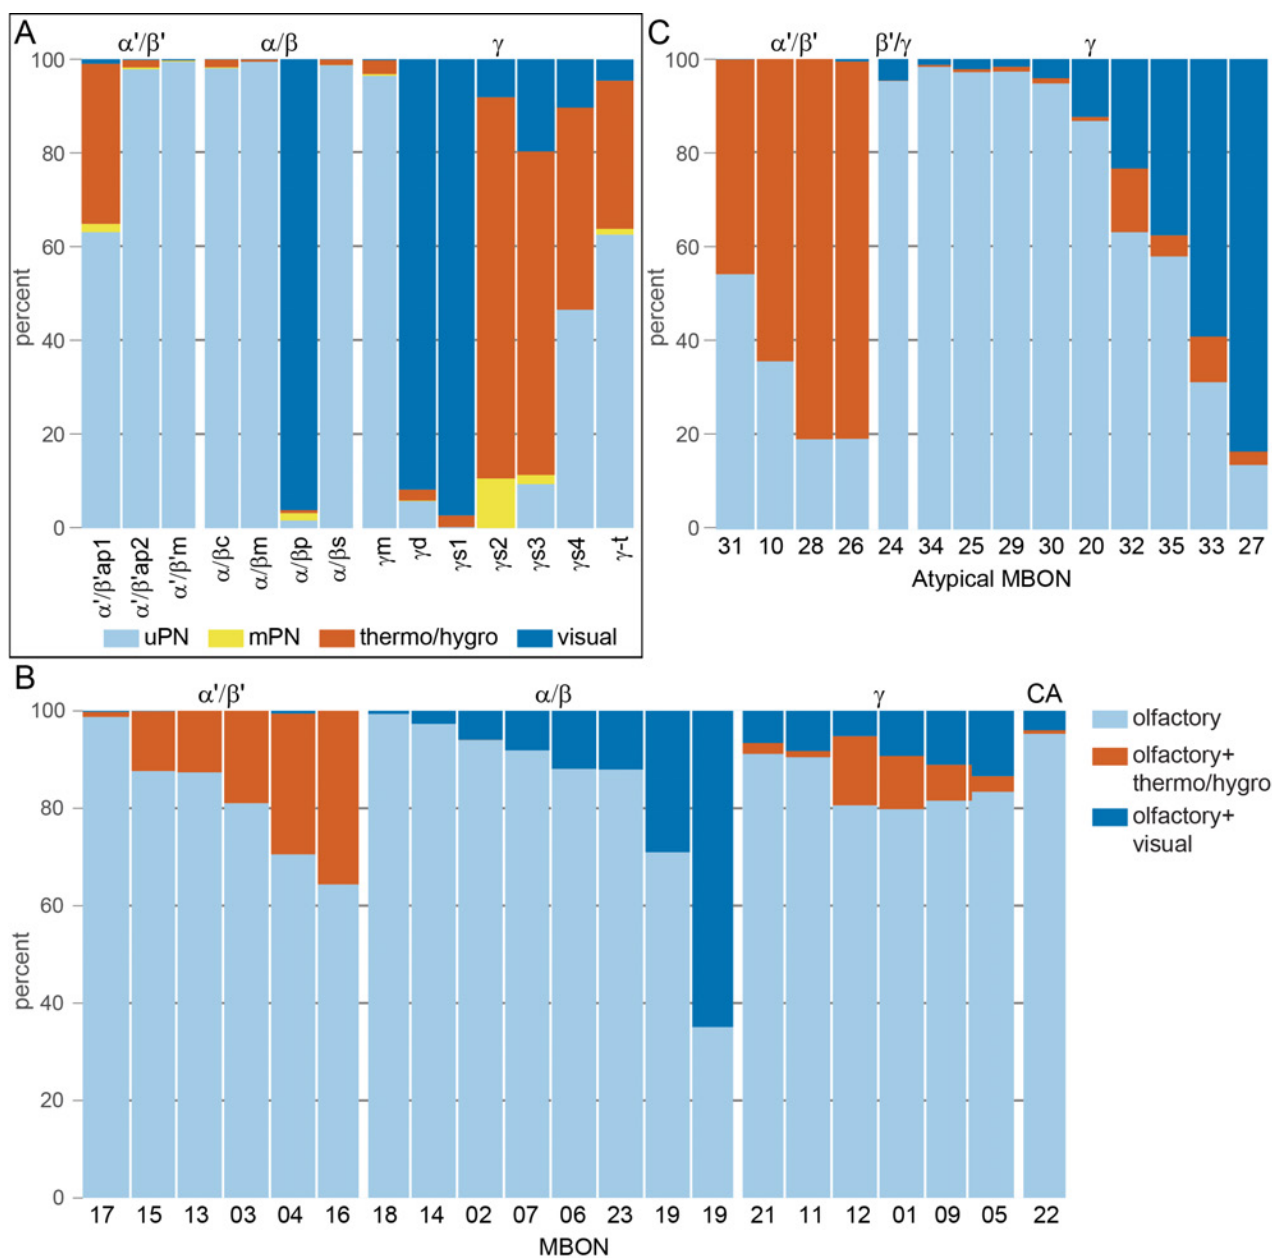

Figure 15-figure supplement 2. PN to KC and KC to MBON connectivity by sensory modality.

(A) Olfactory input from uniglomerular PNs is carried by most of the KC types (α'/β' m, α'/β' ap2, α/β c, α/β m, α/β s, γ m), but thermo-hygro-sensory and visual inputs are conveyed by specific KC subtypes. In particular α/β p, γ d and γ s1 KCs carry substantial fractions of visual input, and α'/β' ap1, γ s2-4 and γ t KCs convey thermo-hygro-sensory information. (B) Within the α'/β' , α/β and γ lobes, the amount of non-olfactory input to different MBONs varies across MBON types due to differential KC innervation. MBONs innervating the α'/β' lobe received variable amounts of thermo-hygro-sensory input due to different levels of α'/β' ap1 innervation. Visual input varies across the α/β MBONs due to different amounts of α/β p KC input. The γ lobe, in contrast, has a more uniform distribution of different sensory modalities across its MBONs. (C) Same as (B), but for atypical MBONs. Percentages indicate the number of synapses of a given type divided by the total number of sensory input synapses to each KC type (panel A) or KC synapses to each MBON (panels B and C). Panels B and C reflect KC input to MBONs with the KCs divided into classes according to panel A. In contrast, Figures 15A and 15B show the full input-to-output effective connectivity.

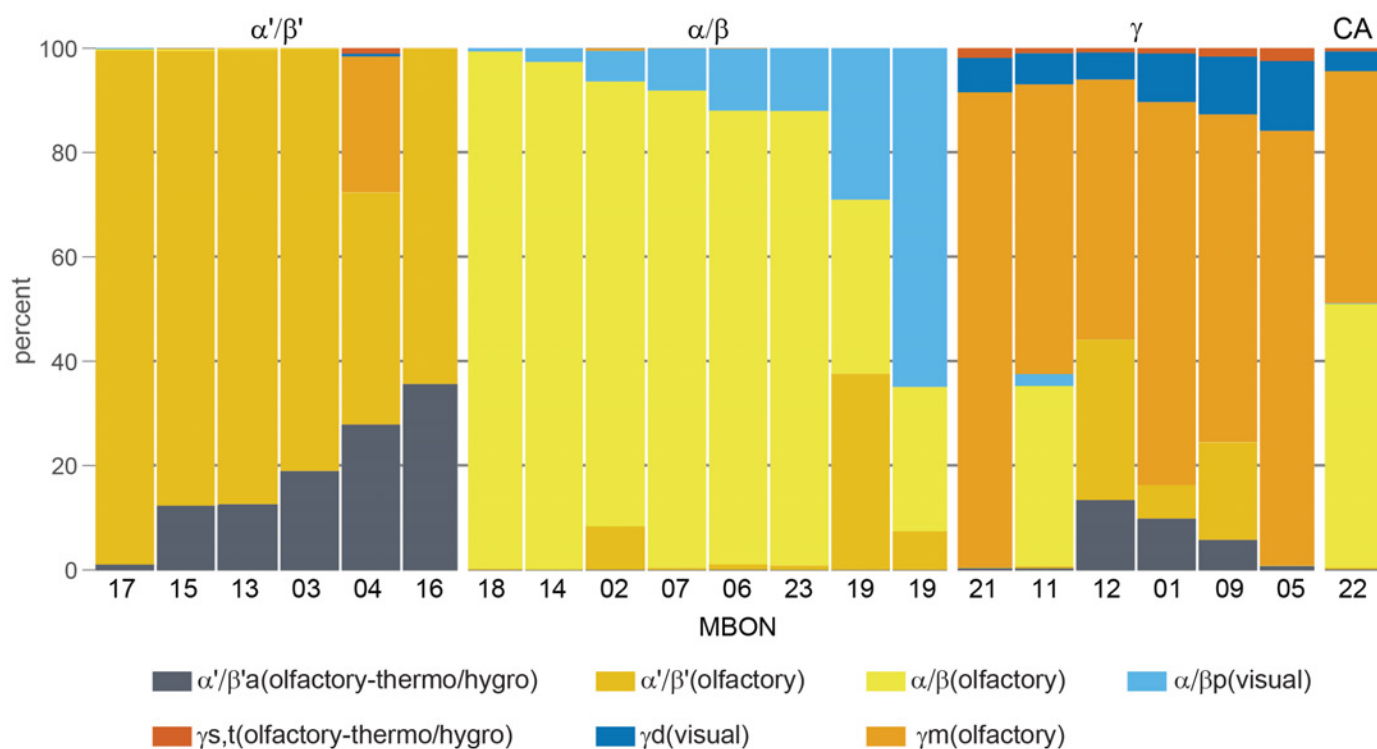

Figure 15-figure supplement 3. MBON connectivity by KC type.

Percentage of input to typical MBONs by KC type. Similar to Figure 15-figure supplement 2C, except that the KCs have been divided by lobes as well as by sensory modality. MBONs exhibit different biases toward KC types, which underlies differences (as shown in Figure 15-figure supplement 2) in the proportion of effective input they receive from each sensory modality. We also observe a few instances of MBONs receiving substantial input from KCs in unexpected (relative to prior findings) lobes, including the large percentage of γ KC input to MBON04 ($\beta'2mp_bilateral$), and the large percentages of α'/β' input to one of the two MBON19s ($\alpha 2p3p$). It is unknown if these unexpected connections are stereotyped.

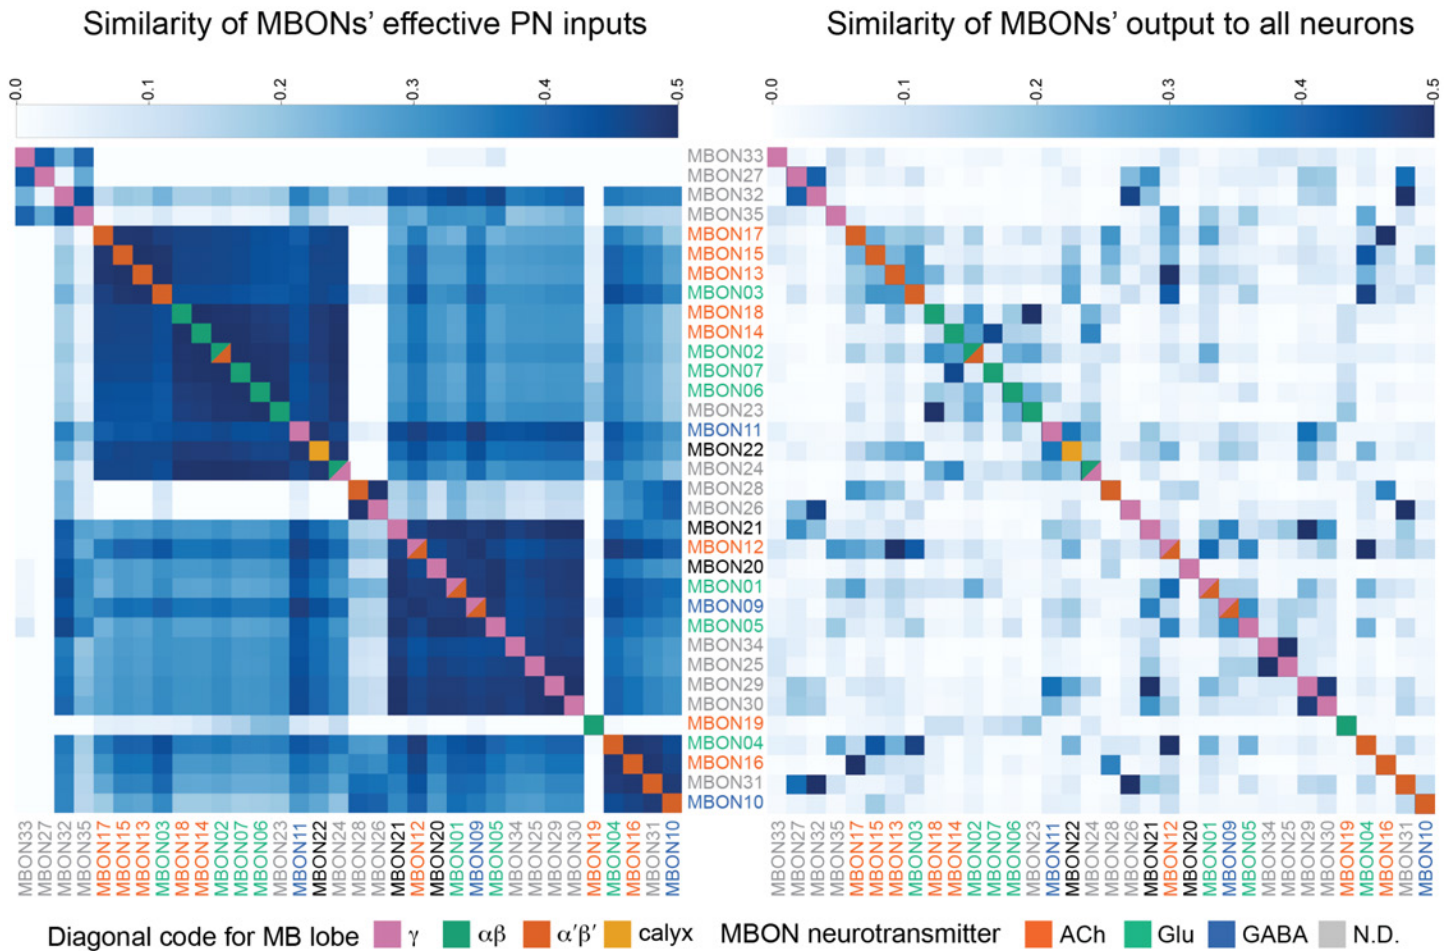

Figure 16. MBON input and output similarity structure.

A comparison of MBON inputs and outputs through the lens of similarity structure. Left: cosine similarity of MBONs based on their effective PN inputs via KCs (computed as in Figure 15). Each cell of the heat map indicates the input similarity of the indicated pair of MBONs. A value of 0.5 indicates that the PN subpopulations conveying input to the two MBONs via KCs are half overlapping and half disjoint. Right: cosine similarity of MBONs based on their outputs to all neurons (unnamed neuronal fragments have been excluded). The resemblance between the left and right plots suggests that MBON outputs preserve some of the parallel structure in the PN-KC-MBON pathway. In each plot, the square in the diagonal is color-coded to indicate the MB lobe in which that MBON's dendrites lie. The MBON names are color-coded to indicate their neurotransmitter, as indicated.

Figure 16-figure supplement 1. MBON output similarity by lobe.

Cosine similarity of MBONs based on the similarity of their outputs to all neurons (unnamed neuronal fragments have been excluded). Each cell of the heat map indicates the output similarity of the indicated pair of MBONs. This is the same data as plotted in Figure 16, except that the MBONs are organized by lobe, shown in the same order as in Figure 15. The preservation of lobe-wise sensory input structure in the MBONs suggests that MBONs may mediate multiple parallel pathways that transform sensory information into behavioral output. The MBON names are color-coded to indicate their neurotransmitter, as indicated.

Figure 16-figure supplement 2. Correlation of MBON output and PN input similarity.

Scatter plot of MBON output similarity vs. similarity of their inputs from PNs, quantifying the relationship between the structure of MBON outputs and their sensory inputs. Each point represents a pair of MBONs from different compartments. Output similarity is computed using the cosine similarity of outputs, as in Figure 16. PN input similarity is computed using cosine similarity of effective PN inputs, as in Figure 16. The highest ten points on the y-axis correspond to the following pairs (fewer than ten listed due to multiple MBONs of the same type): MBON31($\alpha'1$) and MBON32 ($\gamma'2$). MBON26 ($\beta'2d$) and MBON31 ($\alpha'1$), MBON12 ($\gamma'2\alpha'1$) MBON13 ($\alpha'2$). MBON04 ($\beta'2mp_bilateral$) and MBON12 ($\gamma'2\alpha'1$), MBON26 ($\beta'2d$) and MBON32 ($\gamma'2$), MBON07 ($\alpha'1$) and MBON14 ($\alpha'3$).

Figure 16-figure supplement 3. MBONs clustered by output similarity.

Cosine similarity between each MBON type and their target population. The ordering of MBONs was determined using average clustering. Unlike Figure 16 or Figure 16-figure supplement 1, the ordering of the MBONs in this figure does not take into account input structure or anatomical structure, allowing for unbiased grouping of MBONs based on their outputs. This reveals some clusters of MBONs with convergent outputs that span multiple lobes. Only named neurons were considered in the target population. MBON names are color-coded to indicate their neurotransmitter.

Figure 16-figure supplement 4. MBON morphologies grouped by output similarity.

Radial dendrogram shows that MBONs with similar downstream connectivity innervate different compartments. A dendrogram based on the MBON cosine similarity matrix (Figure 16-figure supplement 3) was extracted and the morphologies of the MBON in each group were plotted. Colored dots match the colors of the MBONs in the morphology images. MBONs can have similar downstream connectivity regardless of whether they innervate the same (MBONs 16, 17 and 28) or different (MBONs 23, 18, 06 and 02) compartments. The asterisk indicates MBONs (MBON10, 13, 15, 20 and 33) that could not be grouped with another partner; they are singletons where their downstream connectivity is different from all other MBONs.

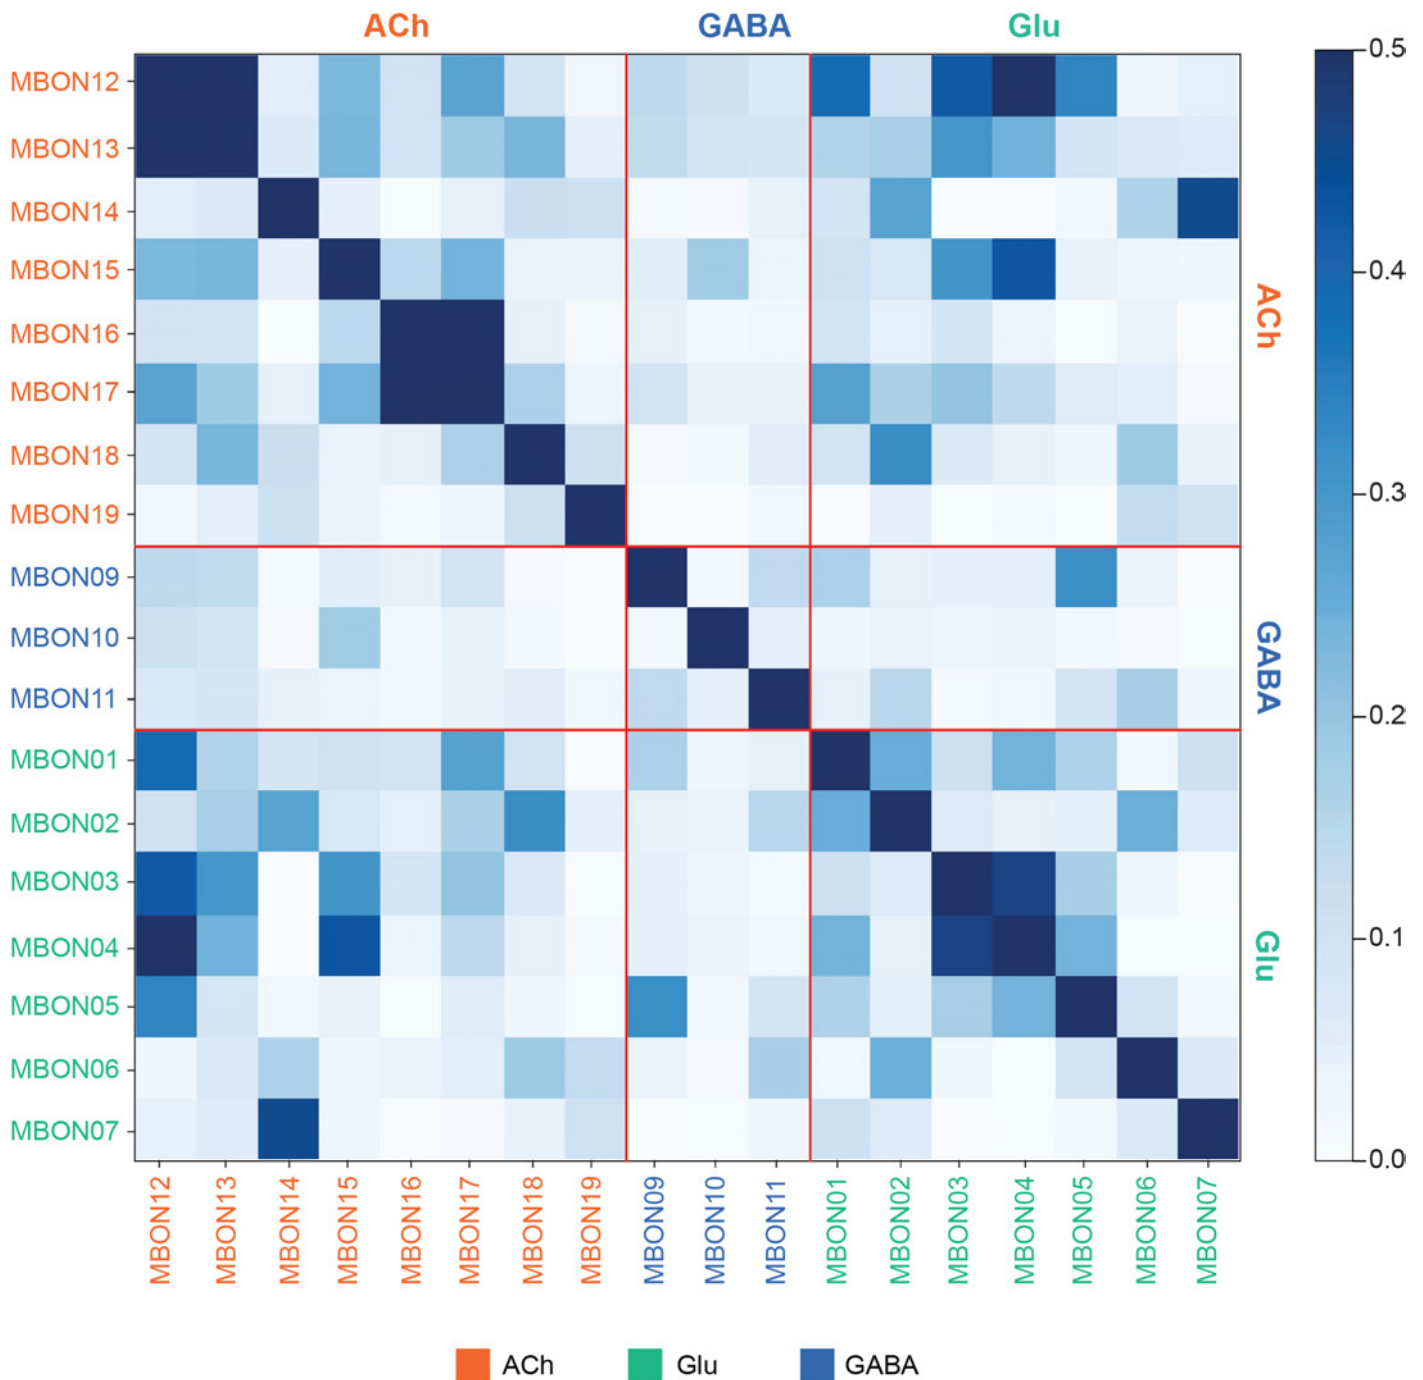

Figure 17. MBON output similarity by neurotransmitter.

Cosine similarity of MBON outputs, for MBONs with known neurotransmitter, to all named neurons. MBONs have been grouped by neurotransmitter and then presented in numerical order. There exist many instances of convergent outputs between cholinergic and glutamatergic neurons, suggesting a widespread “push-pull” motif in MBON output convergence patterns. This phenomenon is emphasized in Figure 17-figure supplement 1 and notable examples are explored in further detail in Figure 20-figure supplement 1 and Figure 21-figure supplements 1 and 2. The MBON names are color-coded to indicate their neurotransmitter.

Figure 17-figure supplement 1. MBON output similarity pooled by neurotransmitter.

Average cosine similarity of pairs of MBONs with the indicated neurotransmitters, computed by collapsing the blocks in Figure 17.

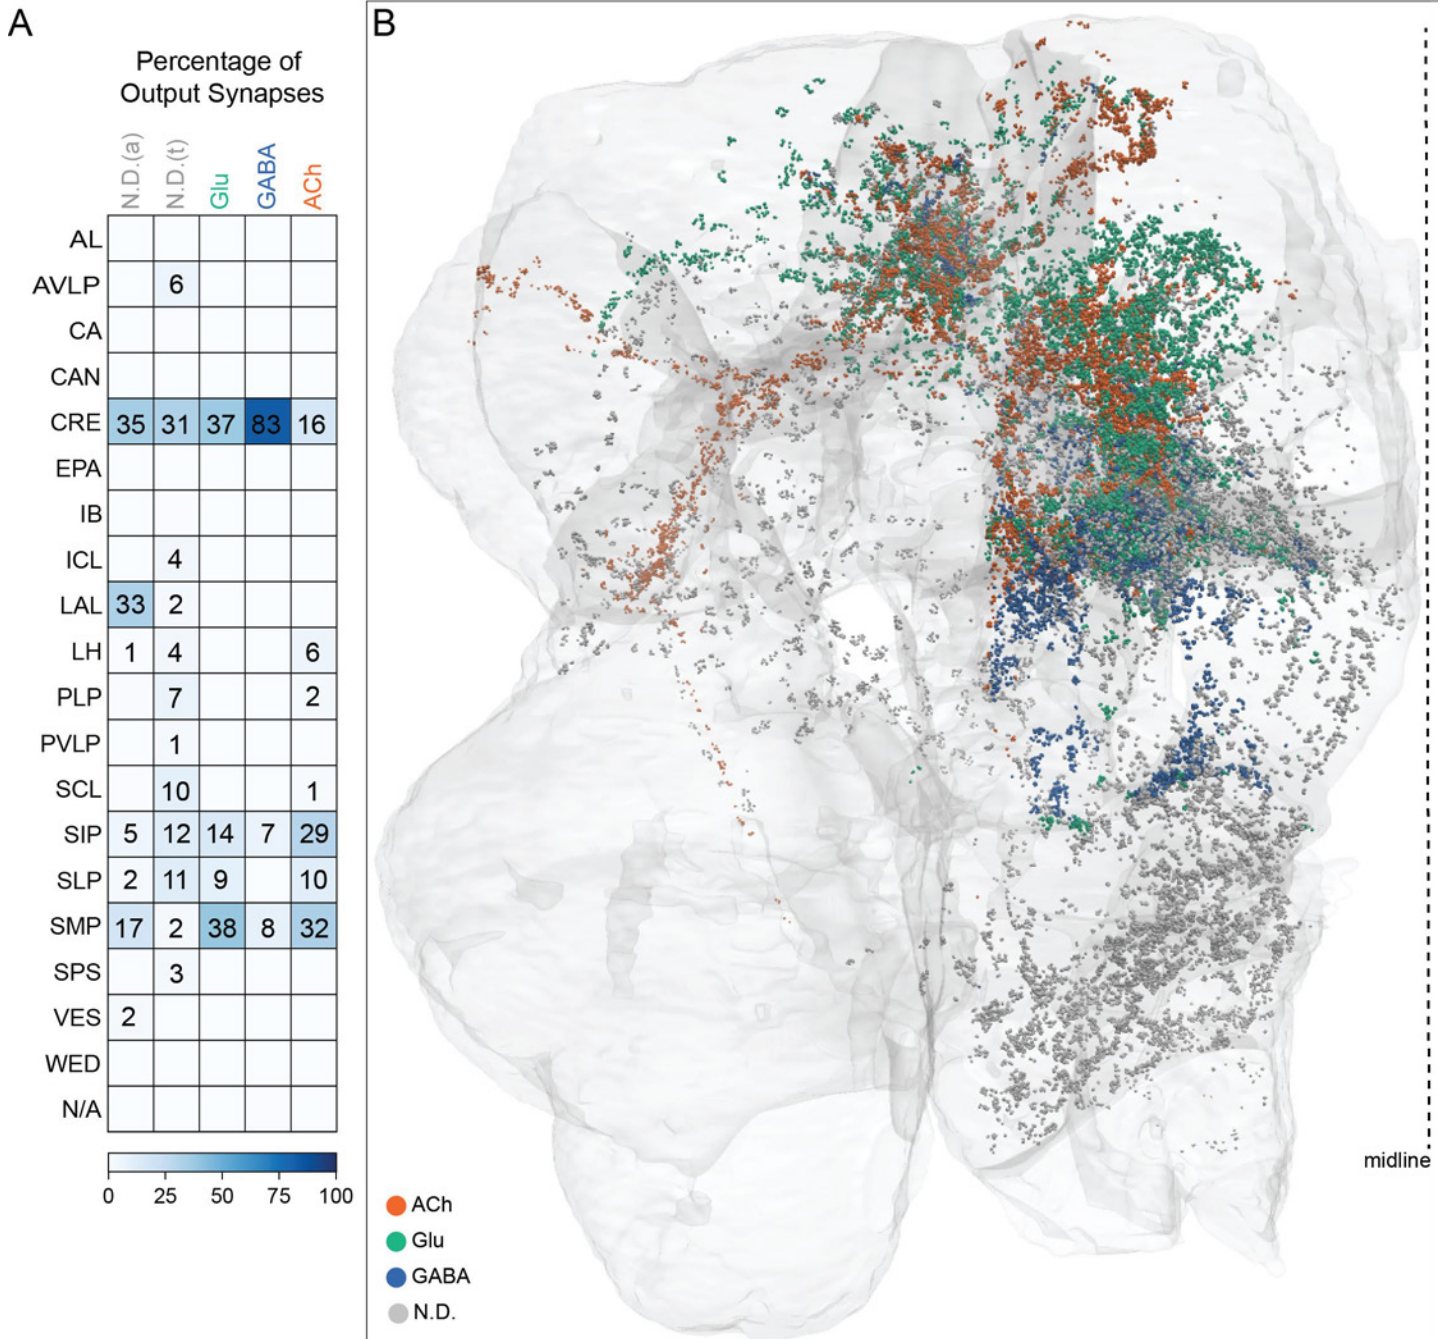

Figure 18. MBON output distribution by neurotransmitter.

(A) Table indicating the percentage of output synapses of each MBON neurotransmitter type that reside in the given brain area; typical (t) and atypical (a) MBONs with undetermined transmitter were analyzed separately. (B) Visualization of the spatial position of MBON output synapses throughout the hemibrain volume, colored by their neurotransmitter type. Figure 18-figure supplement 1 shows the same data presented on separated brain areas.

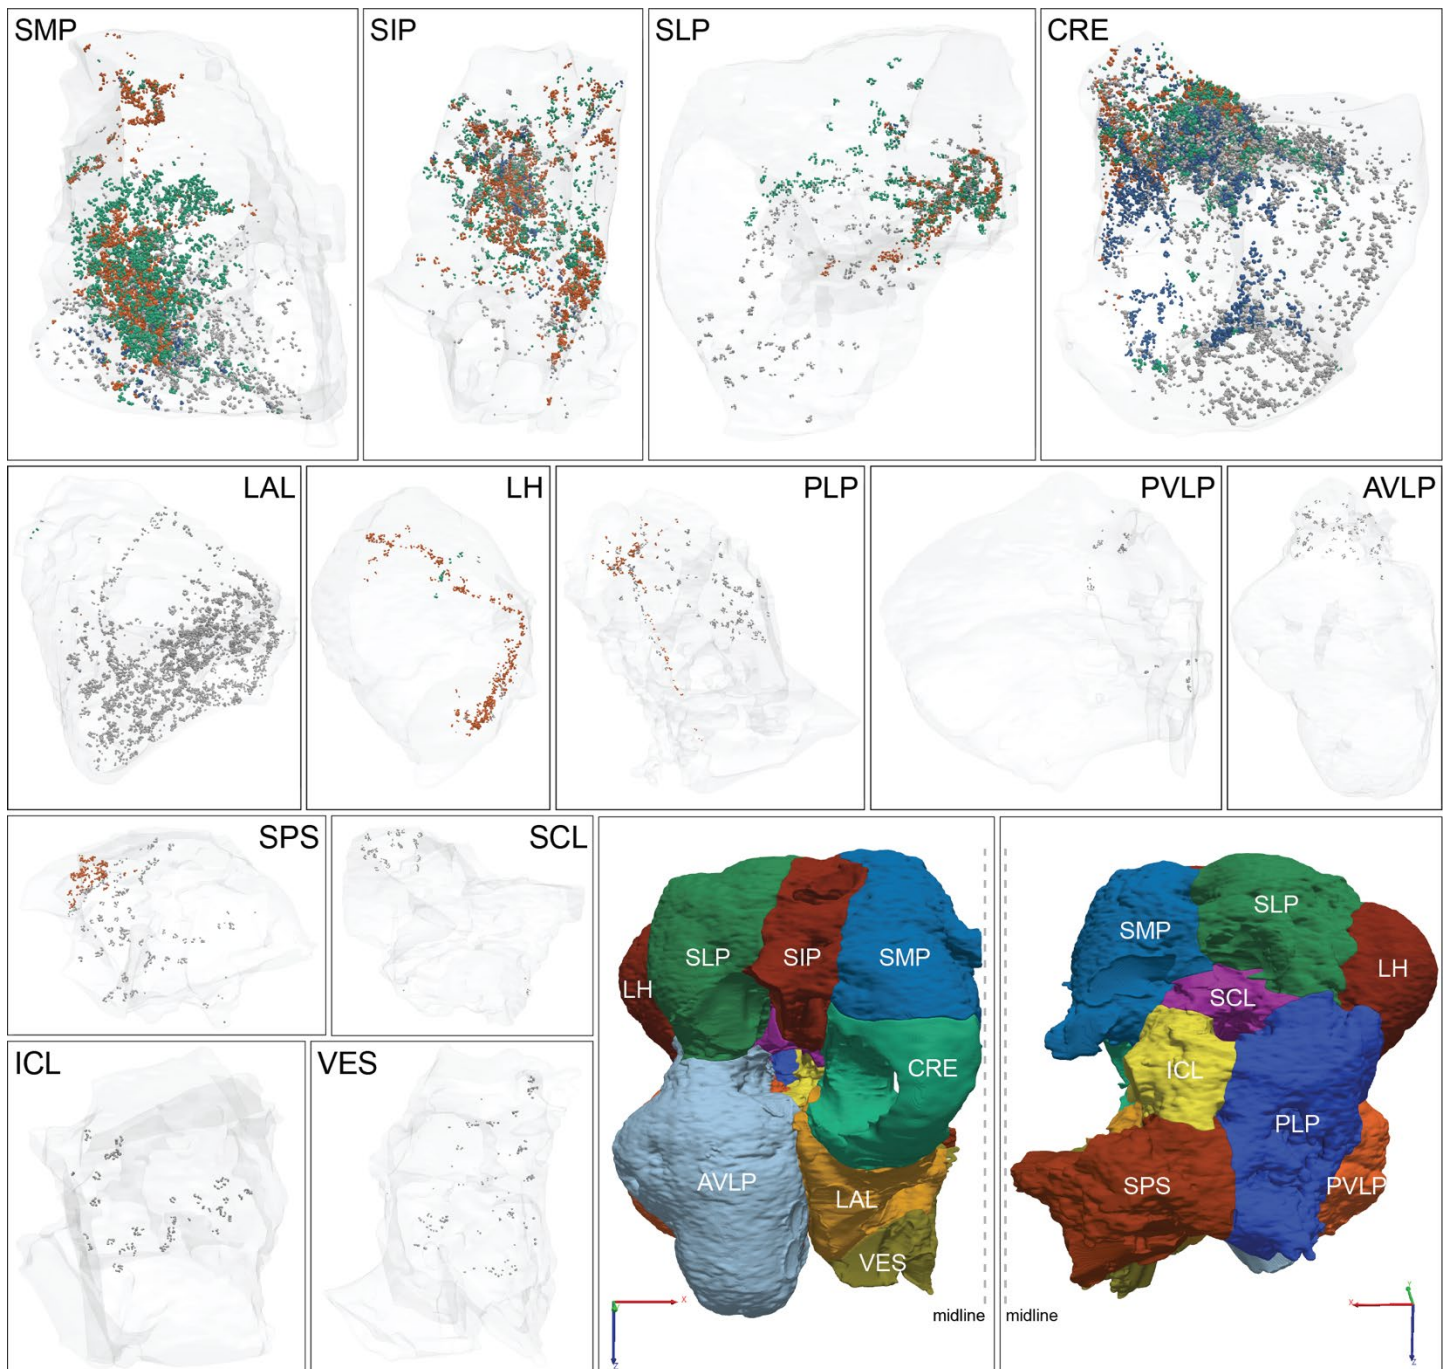

Figure 18-figure supplement 1. MBON output distribution by neurotransmitter presented on separated brain areas. Visualization of the spatial position of MBON output synapses within individual brain areas, as indicated.

Figure 18-figure supplement 2. Distribution of individual MBON outputs by brain region.

MBON outputs to brain areas, grouped by neurotransmitter; typical and atypical MBONs with undetermined transmitter were grouped separately. (Left) The value of each cell indicates the percentage of the given MBON's output synapses that reside in the given brain area. Blank cells indicate values of less than 1%. (Right) The value of each cell indicates the number of the given MBON's output synapses that reside in the given brain region divided by 10 and rounded to an integer. Blank cells indicate brain regions that receive fewer than 10 synapses from the corresponding MBON.

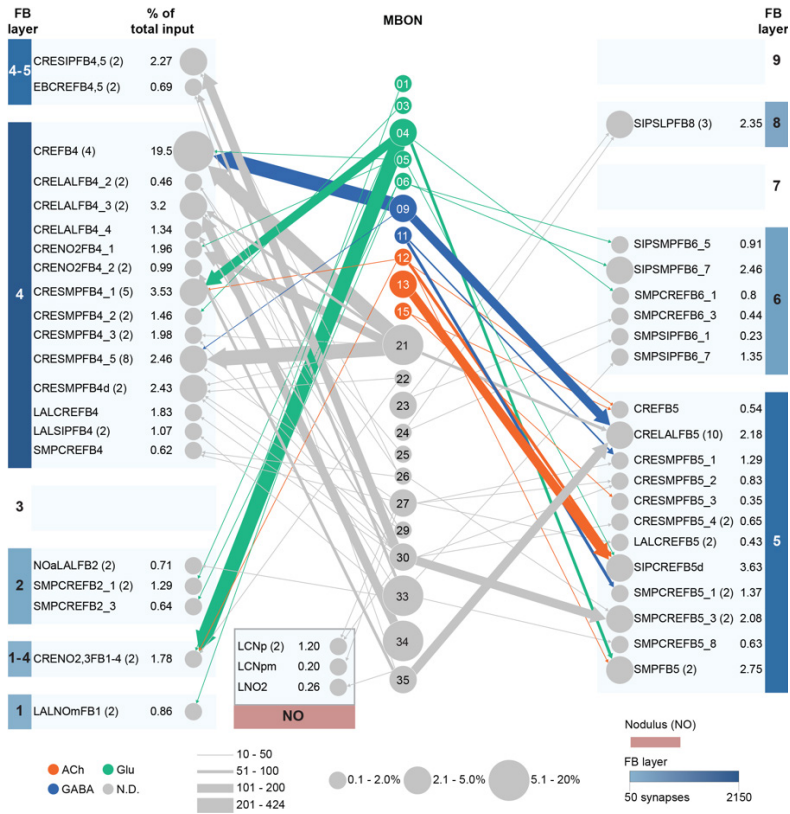

Figure 19. Direct connections from MBONs to the central complex (CX).

In this diagram, the central column shows those MBONs that make direct connections of 10 or more synapses onto the dendrites of CX neurons. Such direct connections predominantly occur on fan-shaped body (FB) neurons. Three cell types of nodulus (NO) cell types are also direct targets (see Figure 22-figure supplement 1A); some FB cell types in layers 1, 2, 3 and 4 that are downstream of MBONs also have arbors in the NO. No direct targets were identified in other CX neuropils such as the ellipsoid body (EB) or protocerebral bridge (PB). The number in the circle indicates the MBON cell type; that is, 01 stands for MBON01. MBONs with numbers up to MBON23 are typical MBONs, while MBONs numbered between MBON24 and MBON35 are atypical. The color of the circle represents the MBON's neurotransmitter while the size of the circle indicates what percent of that MBON's total output (based on synapse number) goes directly to FB neurons. Numbers have been pooled for cases where there are multiple MBONs of the same cell type. The outer columns show FB cell types, arranged by the layer(s) in the FB where their output synapses are located. The name of the cell type and, in parentheses, the number of cells of that type are indicated for those with multiple cells. The percentage of that cell type's input that comes from MBONs is given and is reflected by the size of the circle representing the cell type. All FB neuron types receive less than 5% of their total input from MBONs except for one layer 4 FB neuron type, CREFB4 (FB4R), which receives nearly 20% of its inputs from two MBONs, MBON09 ($\gamma3\beta'1$) and MBON21 (see Figure 22-figure supplement 1B and C). Direct MBON connections to the FB are concentrated in FB layers 4 and 5. Links to each of these FB and NO cell types in neuPrint, listed from FB layer 1 to FB layer 9 and then for the nodulus, are as follows: [LALNOMFB1 \(FB1C\)](#), [CRENO2,3FB1-4 \(FB1H\)](#), [NOaLALFB2 \(FB2A\)](#), [SMPCREFB2_1 \(FB2C\)](#), [SMPCREFB2_2 \(FB2L\)](#), [CRESMPFB4_1 \(FB4A\)](#), [CRENO2FB4_1 \(FB4C\)](#), [CRESMPFB4_2 \(FB4D\)](#), [CRELALFB4_2 \(FB4F b\)](#), [CRELALFB4_3 \(FB4G\)](#), [CRELALFB4_4 \(FB4H\)](#), [LALCREFB4 \(FB4I\)](#), [CRELALFB4_5 \(FB4J\)](#), [LALSIPFB4 \(FB4L\)](#), [CRENO2FB4_2 \(FB4M\)](#), [SMPCREFB4 \(FB4N\)](#), [CRESMPFB4d \(FB4O\)](#), [CRESMPFB4_4 \(FB4P a and FB4P b\)](#), [CREFB4 \(FB4R\)](#), [CRESIPFB4,5 \(FB4X\)](#), [EBCREFB4,5 \(FB4Y\)](#), [LALCREFB5 \(FB5A\)](#), [SIPCREFB5d \(FB5AB\)](#), [SMPCREFB5_1 \(FB5C\)](#), [CRESMPFB5_1 \(FB5D\)](#), [CRESMPFB5_2 \(FB5E\)](#), [CRESMPFB5_3 \(FB5H\)](#), [SMPCREFB5_3 \(FB5I\)](#), [SMPCREFB5 \(FB5J\)](#), [CRESMPFB5 \(FB5K\)](#), [CRESMPFB5_4 \(FB5L\)](#), [CRESMPFB5_5 \(FB5M\)](#), [CRELALFB5 \(FB5V\)](#), [SMPCREFB5_8 \(FB5X\)](#), [SMPSIPFB6_1 \(FB6A\)](#), [SMPCREFB6_1 \(FB6P\)](#), [SIPSMPFB6_5 \(FB6Q\)](#), [SMPSIPFB6_7 \(FB6R\)](#), [SIPSMPFB6_7 \(FB6T\)](#), [SMPCREFB6_3 \(FB6V\)](#), [SIPSLPFB8 \(FB8F a\)](#), [LCNp](#), [LCNpm](#), and [LNO2](#).

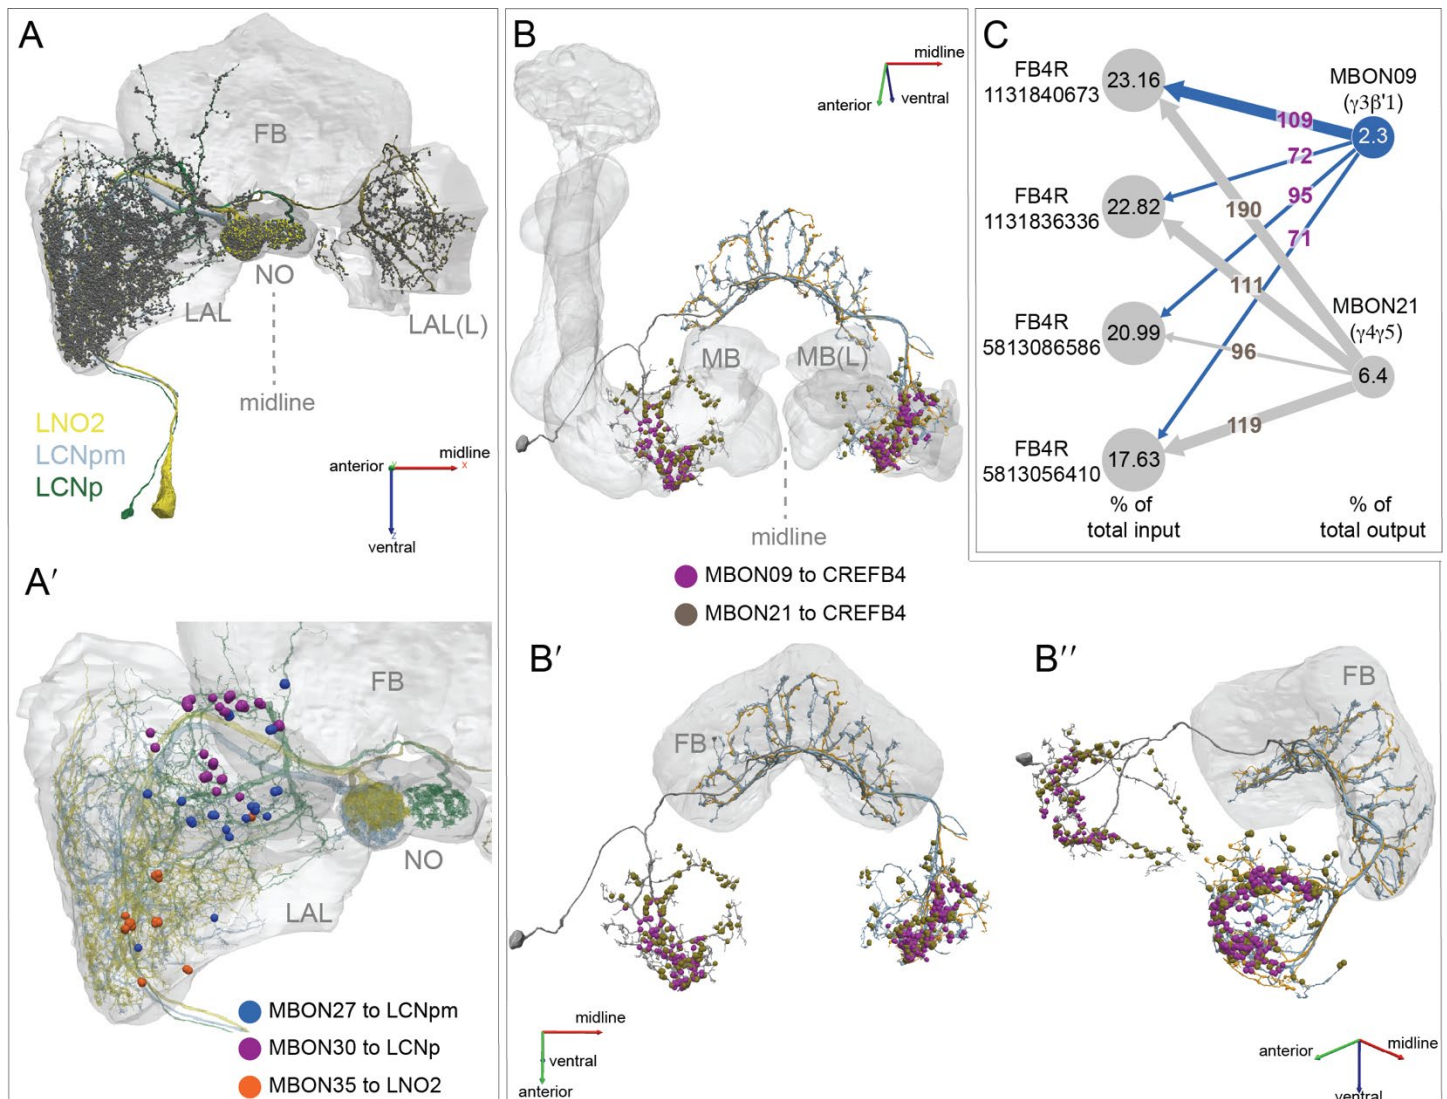

Figure 19-figure supplement 1. The morphology and connectivity of nodulus and CREFB4 neurons.

(A) Morphologies of the LCNp, LCNpm, LNO2 nodulus neurons that are downstream of MBONs. The FB, NO and LAL are shown in grey. Presynaptic sites are shown as yellow dots and postsynaptic sites as grey dots. (A') Higher magnification view, showing the locations of MBON inputs onto these neurons. (B) *CREFB4* (FB4R) neurons are shown with each of the four neurons of this type displayed in a different color. The locations of the synapses CREFB4 (FB4R) cells receive from MBON09 ($\gamma 3\beta'1$) and MBON21 are shown, color-coded. (B', B'') Alternative views of image shown in (B). (C) Diagram of synaptic connectivity. The numbers in the circles that represent the cells indicate, for CREFB4 (FB4R) cells, the percentage of their input that comes from these two MBONs and, for the MBONs, the percent of their output that goes to CREFB4 (FB4R). The numbers in the arrows are the number of input synapses. The neurotransmitters used by MBON21 and CREFB4 have not been determined; MBON09 is GABAergic.

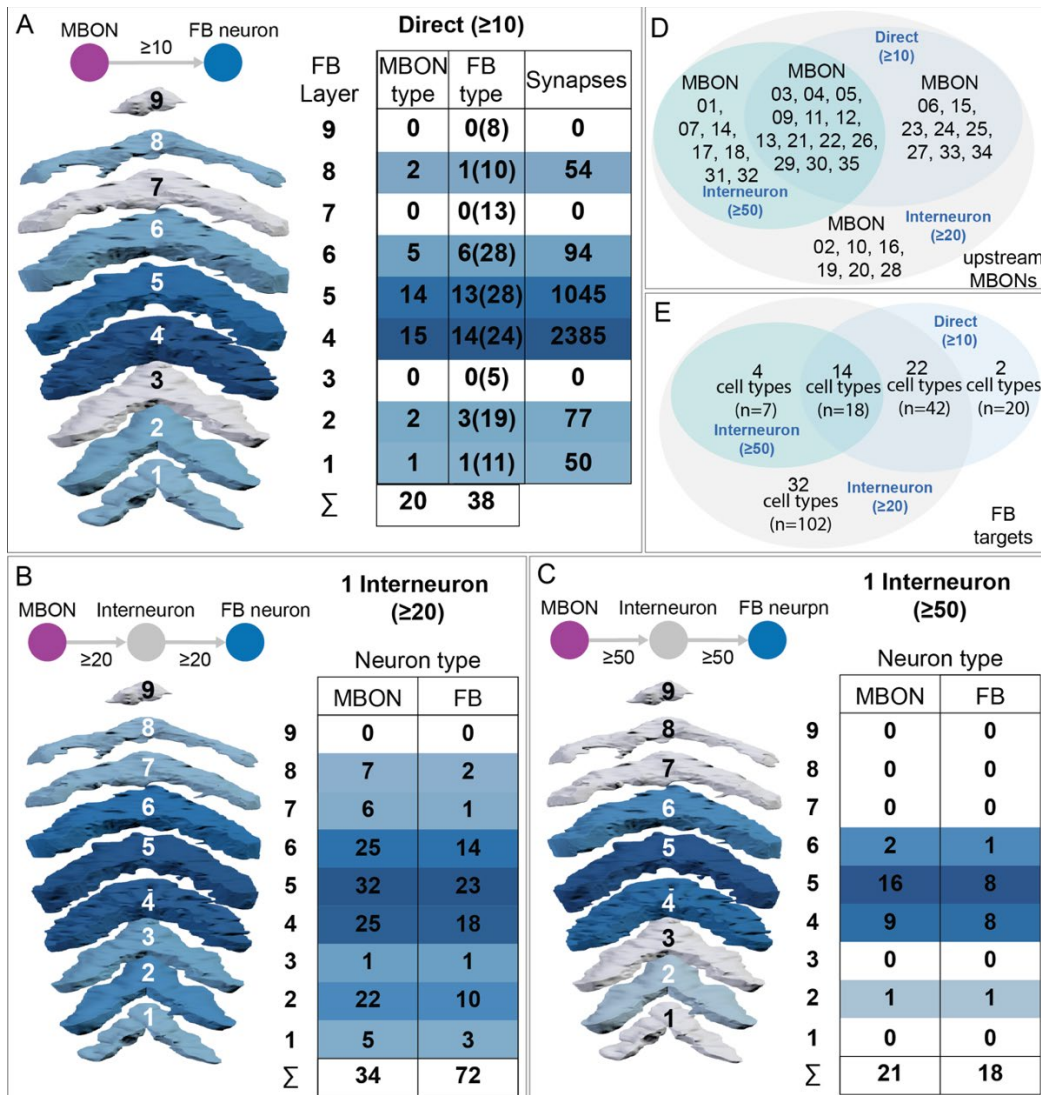

Figure 20. Summary of connections from MBONs to the FB.

Heat maps are shown that compare the strength of connection between MBONs and FB neurons in each FB layer. (A) Direct connections. The number of MBON cell types within each layer that make synapses onto the dendrites of FB neurons, the number of FB neuron types (also within the indicated layers) they connect to, and the total number of MBON to FB neuron synapses are shown for each FB layer. The total number of cell types listed in neuPrint for each FB layer is shown in parentheses. The last row of the table shows the number of different MBON cell types that make direct connections to the FB; some MBONs connect to more than one layer. (B,C) Connections using a single interneuron. The number of MBON cell types connecting to each layer and the number of FB neuron types they connect to are shown. (B,C) Connections between the MBON and the interneuron as well as between the interneuron and the FB neuron are required to have 20 or more synapses (B) or 50 or more synapses (C). The last row of the table shows the number of different MBON cell types that make indirect connections to the FB at this threshold; some MBONs connect to more than one layer. (D) Venn diagram comparing MBON types that are connected to FB neurons directly (as in A); through 1 interneuron with threshold of 20 synapses (as in B); and through 1 interneuron with threshold of 50 synapses (as in C). (E) Venn diagram comparing FB neuron cell types that are targeted by MBONs directly (as in A), through one interneuron with threshold of 20 synapses (as in B), and through one interneuron with threshold of 50 synapses (as in C). The number of cell types and the total number of neurons (n) are indicated.

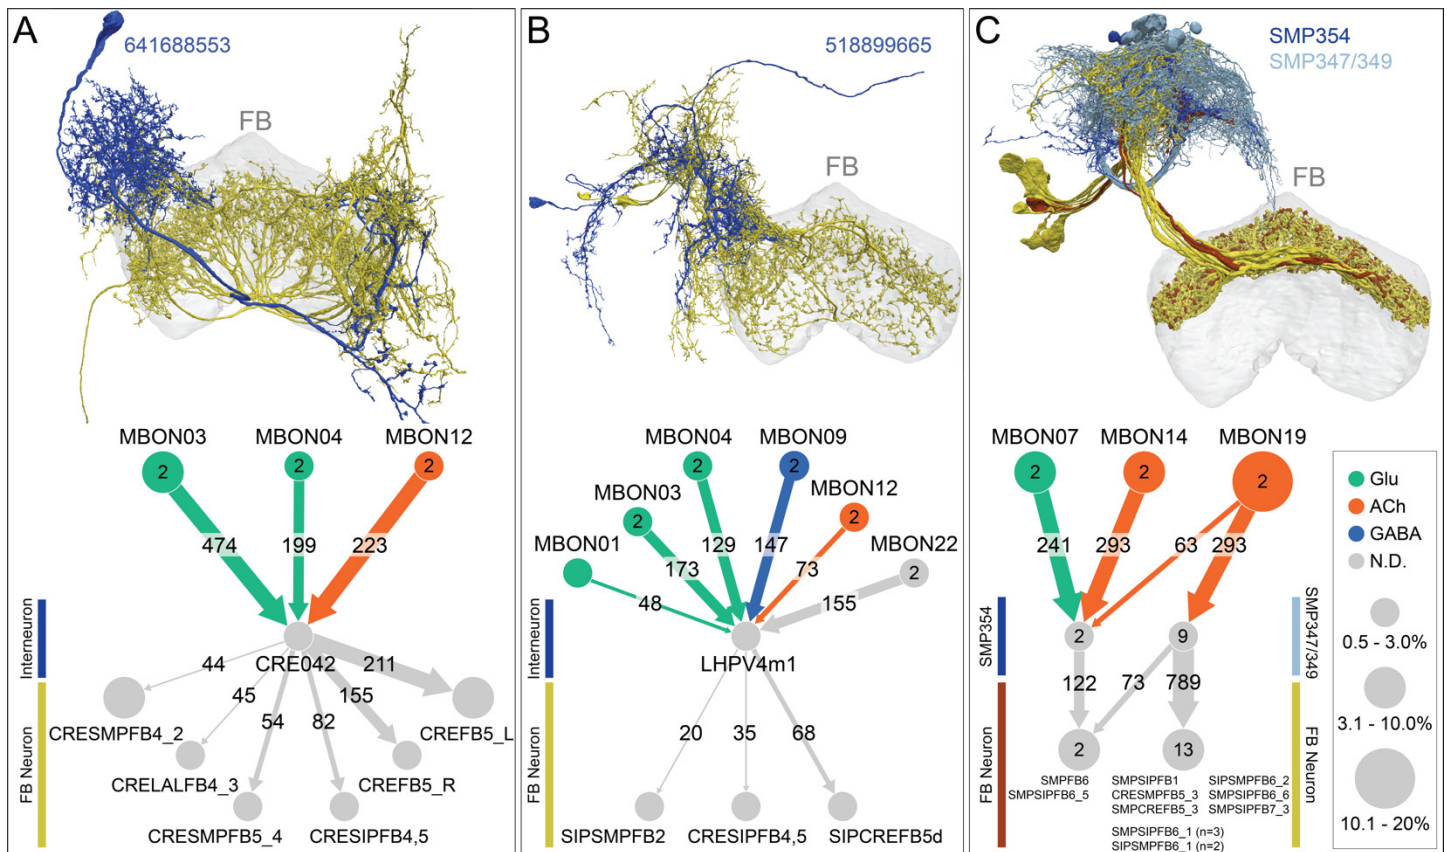

Figure 20-figure supplement 1. Examples of MBON to FB connectivity involving an interneuron.

(A-C) Examples of connectivity patterns observed for connection of MBONs to the FB through an interneuron. At the top of each panel the morphologies of the interneuron (blue) and FB neurons (yellow/brown) are shown. At the bottom of each panel a connectivity diagram is shown, with neurotransmitters color-coded and the size of the circles for MBONs representing the percentage of their outputs that go to the shown interneurons. For FB neurons, the size of the circle represents the percentage of their inputs that come from those interneurons. Note that interneurons in this pathway are often targets of multiple MBONs with neurotransmitters of opposite sign, a so-called “push-pull” arrangement. (A) An interneuron, [CRE042](#), that is strongly connected to MBONs of different valence inputs onto FB neurons of layers 4 and 5: [CRESMFPFB4_2](#) (FB4D), [CRELALFB4_4](#) (FB4H), [CRESIPFB4,5](#) (FB4X), [CRESMPFB5](#) (FB5K), and [CRESMPFB5_4](#) (FB5L) (see Video 27). (B) An interneuron, [LHPV4m1](#), that receives input from six MBON types and connects to three FB neurons of layers 2, 4 and 5, and 5: [SIPSMPFB2](#) (FB2F a), [CRESIPFB4,5](#) (FB4X), and [SIPCREFB5d](#) (FB5AB). No other interneuron connecting to the FB gets input from more different MBONs (see Video 28). (C) This interneuron can be divided into subtypes based on connectivity to α lobe MBONs: [SMP347](#), [SMP349](#), and [SMP354](#), all of which are downstream targets of MBON19 (α 2p3p), which conveys visual information (Figure 15A), but SMP354 consisting of two cells also gets strong input from MBON07 (α 1) and MBON14 (α 3) in a “push-pull” arrangement. All these interneurons convey information mostly to FB layer 6: [SMPSIPFB1,3](#) (FB1A), [CRESMPFB5_3](#) (FB5H), [SMPCREFB5_3](#) (FB5I), [SMPSIPFB6_1](#) (FB6A), [SIPSMPFB6_1](#) (FB6C b), [SMFPFB6](#) (FB6D), [SIPSMPFB6_2](#) (FB6E), [SMPSIPFB6_5](#) (FB6I), [SMPSIPFB6_6](#) (FB6K), and [SMPSIPFB7_3](#) (FB7F) (see Video 29). Note these FB neurons contain 7 of the 9 cells in cluster 31 of Figure 34A.

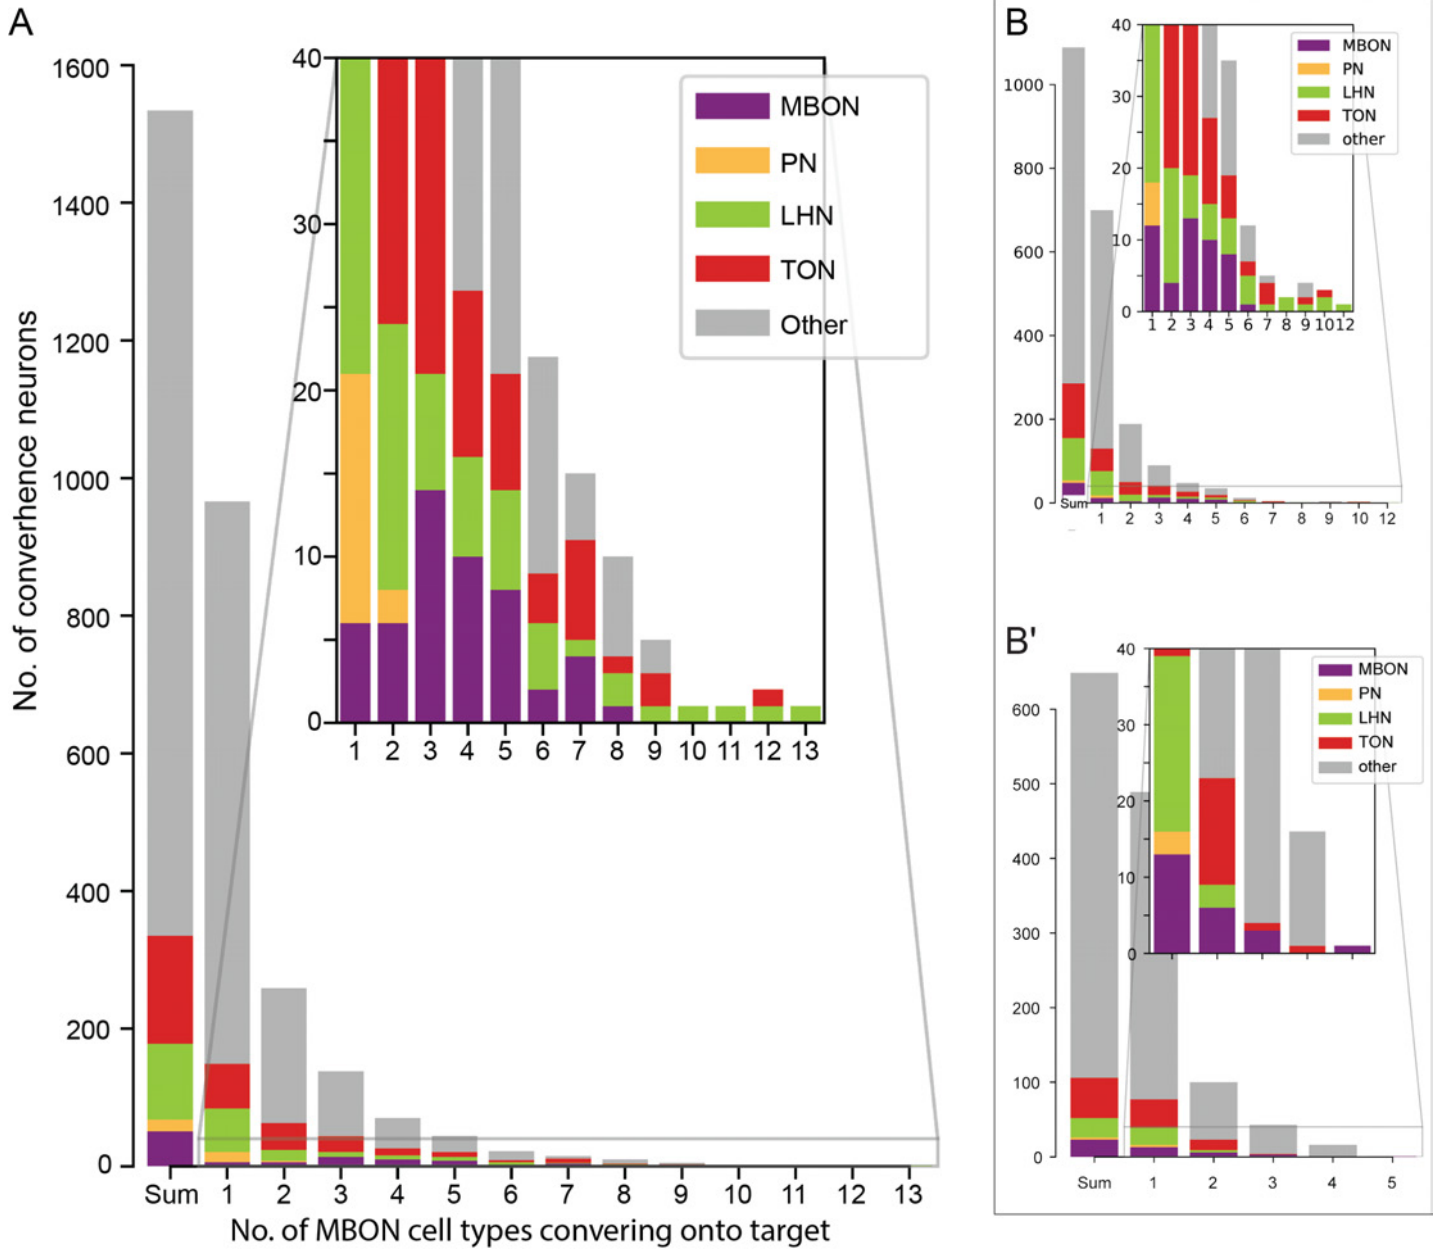

Figure 21. Downstream targets of MBONs often receive input from more than one MBON.

(A) About 1550 neurons are downstream (including axo-axonal connections) of one or more of the 34 MBON cell types when a threshold of 10 synapses is used. Among them, about 600 are downstream of at least 2 MBON cell types and are therefore capable of integrating information from multiple MBONs. The inset shows an expanded view of the indicated portion of the plot. These neurons include a range of well-characterized neuron types, including MBONs, olfactory projection neurons (PNs), lateral horn neurons (LHNs), and third order olfactory neurons (TONs; downstream targets of PNs outside the LH) as well as less characterized neurons (other). Among the neurons that receive input from 10 or more MBON types, LHNs are heavily over-represented. (B, B') The distribution shown in (A) has been divided into two separate histograms, one showing neurons downstream of multiple typical MBONs, in which atypical MBONs have not been counted (B), and one showing neurons downstream of multiple atypical MBONs, in which typical MBONs have not been counted (B'). The insets show expanded views of the indicated portions of each plot. Atypical MBONs show less convergence than the typical MBONs and do not preferentially converge onto LHNs.

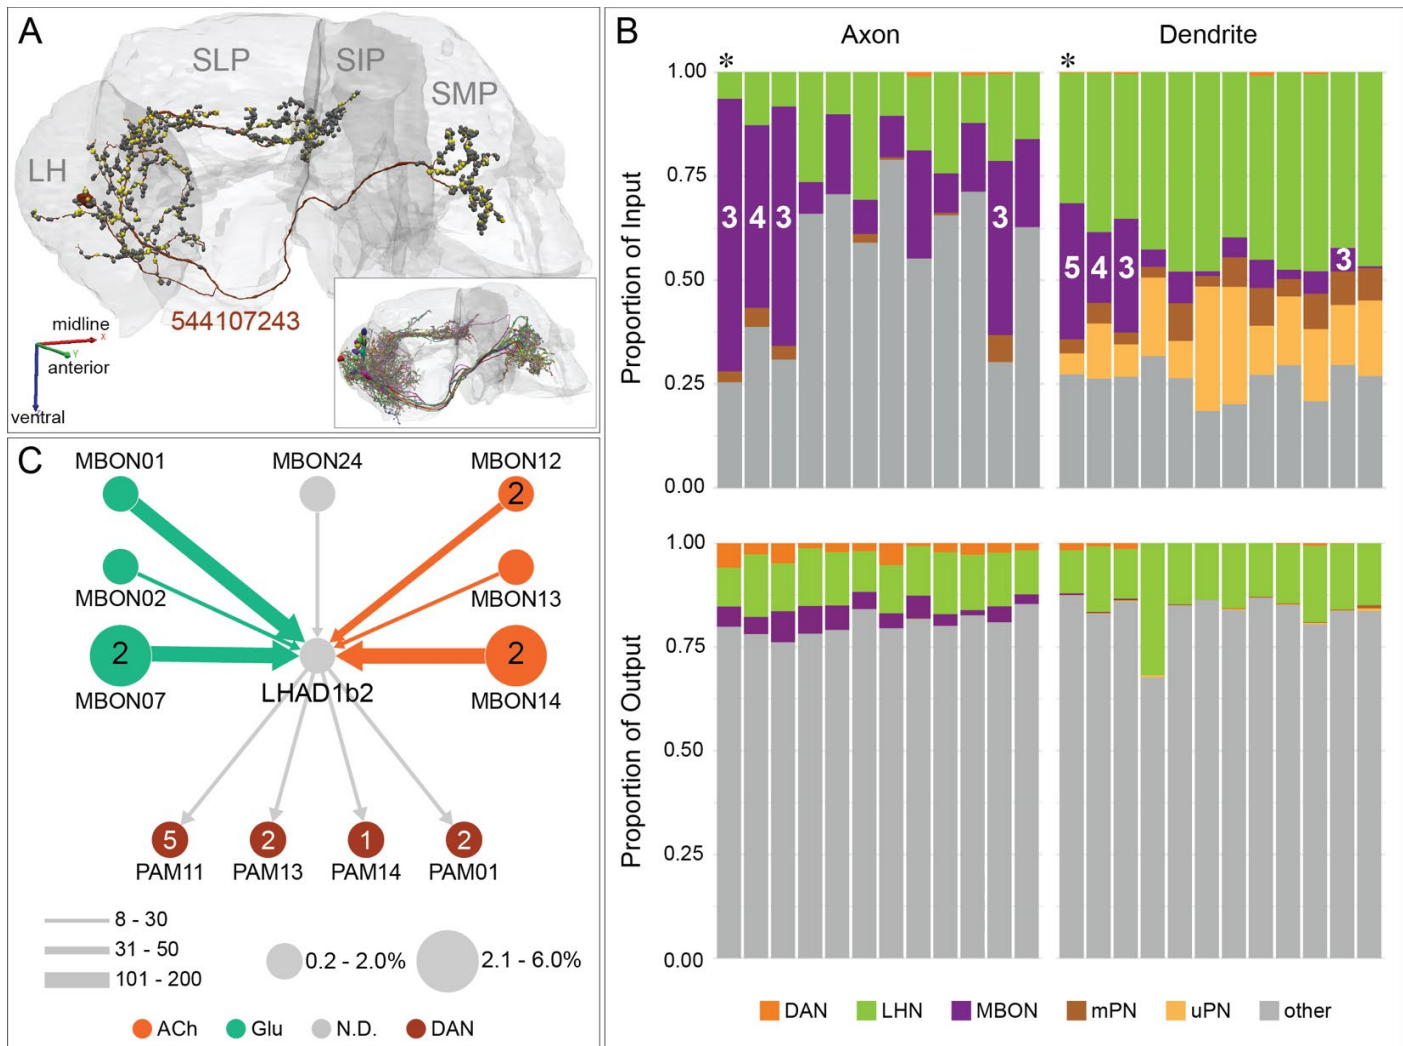

Figure 21-figure supplement 1. A LH neuron downstream of seven MBON types.

The previously reported LH output neuronal type (LHAD1b2; Dolan et al., 2019) acts as a site of integration of innate and learned information. (A) The morphology of a [LHAD1b2_d](#) neuron (544107243) is shown in maroon, with its presynaptic and postsynaptic sites represented by yellow and grey dots, respectively. The inset shows the morphologies of all twelve neurons of this cell type: [LHAD1b2_a](#): 673426956 and 544107335; [LHAD1b2_b](#): 5813022459, 573683438 and 483017681; [LHAD1b2_c](#): 5813052205, 543321179 and 574040939; [LHAD1b2_d](#): 544107243 and 730562988; [LHAD1c1](#): 729867599; and [LHAD1c2](#): 673426956. (B) Histograms of the proportion of inputs to (top) and outputs from (bottom) each of the twelve LHAD1 neurons from various classes of cells are shown, color coded. These connections are divided into two groups based on the positions on the neurons' arbors where they occur, labeled as Axon and Dendrite, based on the distribution of pre- and postsynaptic sites although all its arbors are mixed; the neuron order is the same in all histograms. The number of different MBON types innervating individual LHAD1 neurons varies; the number of MBON types providing input is indicated for those receiving input from three or more types. The neuron (544107243) shown in (A) and (C) is marked with an asterisk. (C) A connectivity diagram of the [LHAD1b2_d](#) neuron displayed in (A) is shown. This neuron receives input from seven MBON types and its downstream targets include four DAN cell types. The transmitters used by the MBONs are color-coded, the thickness of the arrows reflects synapse number, and the sizes of the circles that represent the MBONs reflects the percentage of their output directed to this LHAD1b2_d cell. The size of the circle representing LHAD1b2_d indicates the proportion of its total input that is derived from MBONs and the size of the circles representing the DANs indicate the fraction of their input provided by the LHAD1b2_d cell.

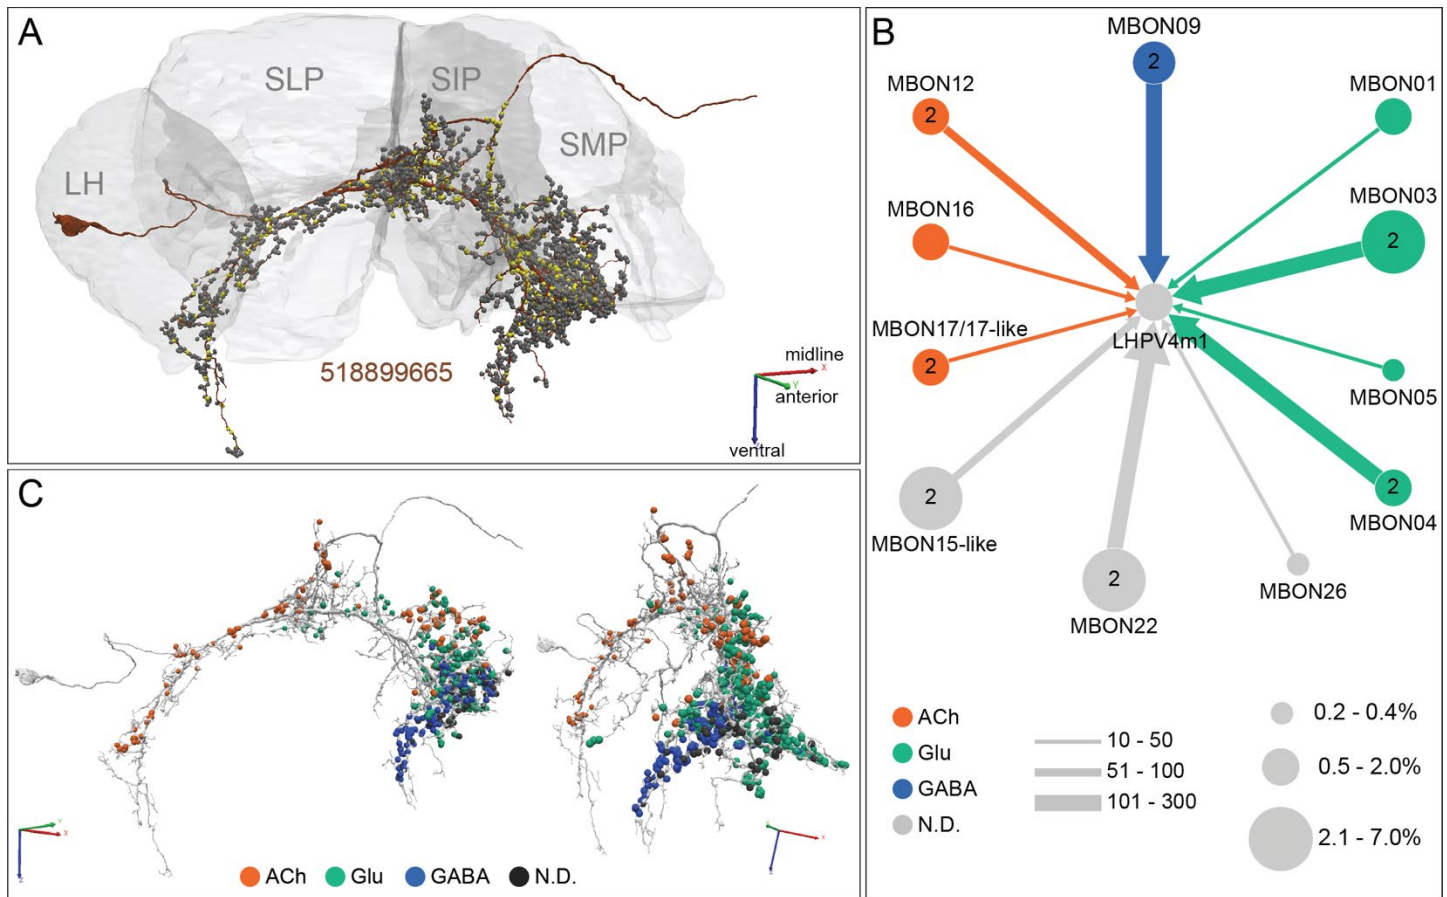

Figure 21-figure supplement 2. A neuron downstream of 11 MBON types.

This neuron [LHPV4m1](#) (518899665) provides an extreme example of a neuron that integrates input from different MBON cell types. (A) The morphology of the neuron is shown in maroon, with its presynaptic and postsynaptic sites represented by yellow and grey dots, respectively. (B) Diagram showing the strengths of input from eleven different MBONs. The transmitters used by the MBONs are color-coded, the thickness of the arrows reflects synapse number, and the sizes of the circles that represent the MBONs reflect the percentage of their output directed to this neuron. (C) Distribution of sites of MBON input to the neuron, color-coded by MBON neurotransmitter type. Note that connections from MBONs with different neurotransmitters are segregated along the neuron's different arbors; for example, cholinergic inputs are concentrated in its posterior branches.

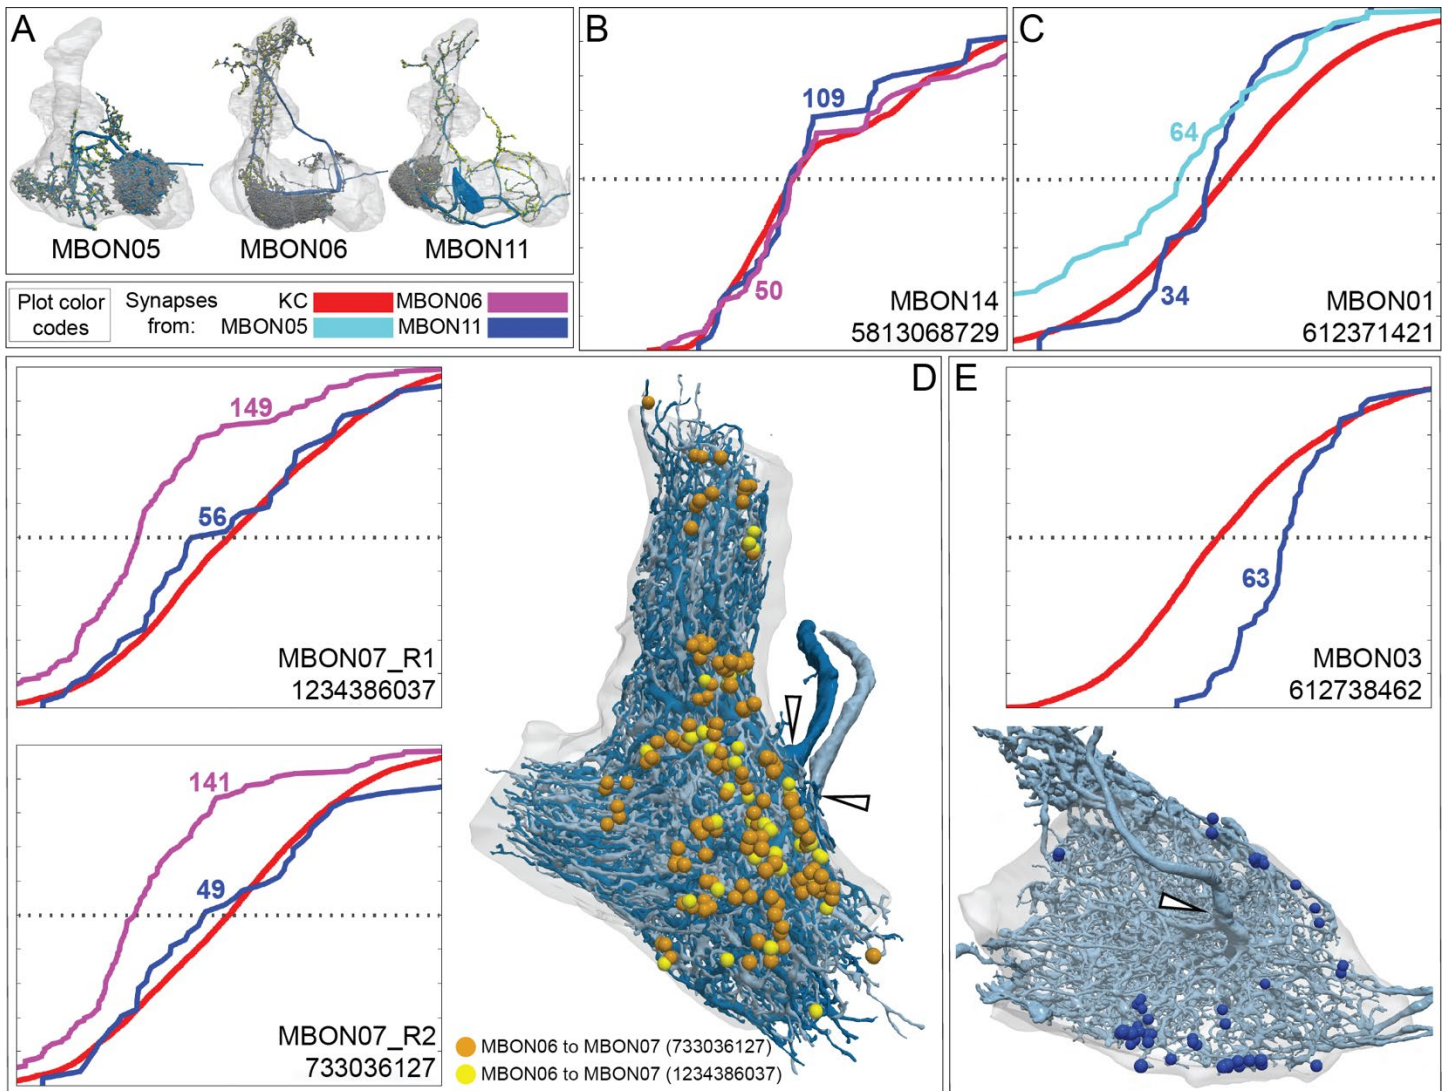

Figure 22. Spatial distribution of synapses from feedforward MBONs onto the dendrites of other MBONs.

(A) The three MBON types that make feedforward connections to other compartments within the MB lobes are shown. Neurons are shown in blue with presynaptic and postsynaptic sites shown as yellow and grey dots, respectively. (B-E) The cumulative fraction of synaptic connections from a feedforward MBON to its target is plotted as a function of the normalized distance from the root of the target MBON's dendritic tree, on a linear scale from 0 to 1. The name of the target neuron is given in the lower right corner of the panel. The horizontal dotted line indicates the distance from the root of the target MBON's dendritic tree at which the half of the synapses from KCs to that MBON have occurred. The lines in these graphs are color-coded as indicated by key shown below panel A. The numbers indicate the total number of synapses between the neuron of the same color and the target MBON. (B) The synapses from MBON06 ($\beta1 > \alpha$) and MBON11 ($\gamma1pedc > \alpha/\beta$) onto MBON14 in $\alpha3$ have a similar spatial distribution as MBON14's synapses from KCs. (C) MBON01's dendrites in $\gamma5$ receives synaptic connections from MBON11 closer to MBON01's dendritic root than KC inputs, a bias even more pronounced in the distribution of synapses MBON01 ($\gamma5\beta'2a$) receives from MBON05 ($\gamma4 > \gamma1\gamma2$). (D) The two MBON07 cells in the $\alpha1$ compartment each receive synaptic input from MBON06 ($\beta1 > \alpha$) at sites close to the root of their dendrites (hollow arrowheads); in contrast, MBON11's synapses onto the MBON07s have a similar distribution as the input the MBON07s receive from KCs. (E) MBON03 ($\beta'2mp$) receives synaptic input from MBON11 shifted further from its dendritic root (hollow arrowhead) than the input it receives from KCs.

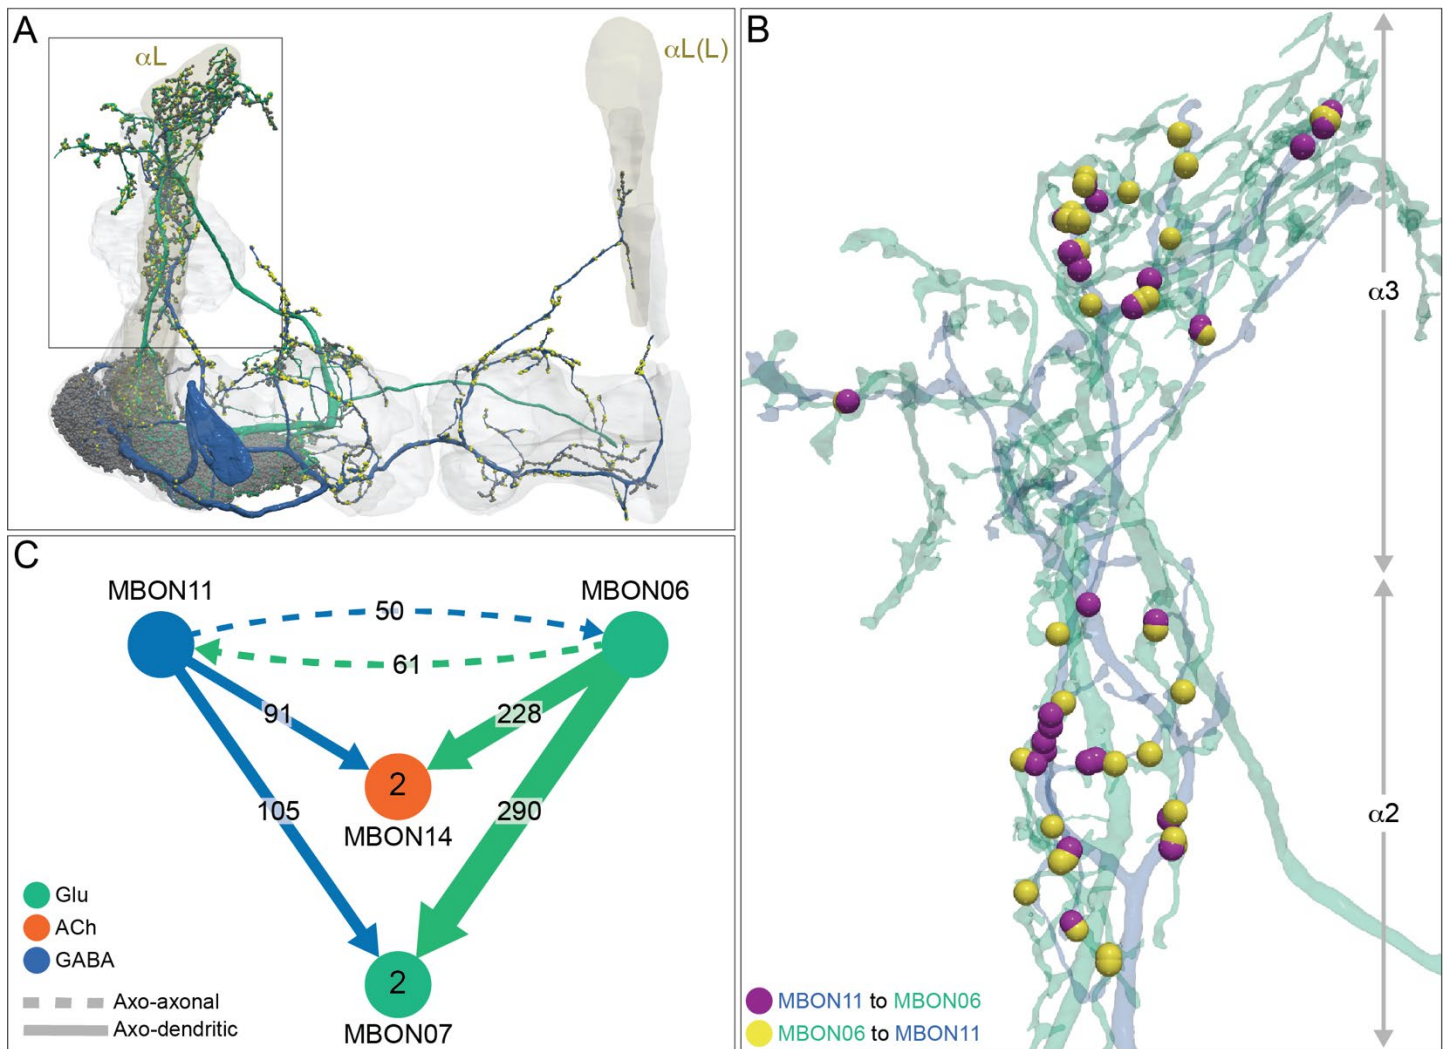

Figure 22-figure supplement 1. MBON06 and MBON11 make reciprocal axo-axonal connections in the α lobe. (A) MBON06 ($\beta 1 > \alpha$; green) and MBON11 ($\gamma 1 \text{ ped} > \alpha / \beta$; blue) send axonal processes to the $\alpha 2$, $\alpha 3$ and, to a lesser extent, $\alpha 1$ compartments. (B) MBON06 and MBON11 make reciprocal axo-axonal connections, mostly in the $\alpha 2$ and $\alpha 3$ compartments. The positions of these synapses are shown, color coded. (C) Diagram of a subset of connections involving MBON06 and MBON11, which both also make axo-dendritic connections onto MBON07 ($\alpha 1$) and MBON14 ($\alpha 3$) inside the MB lobes.

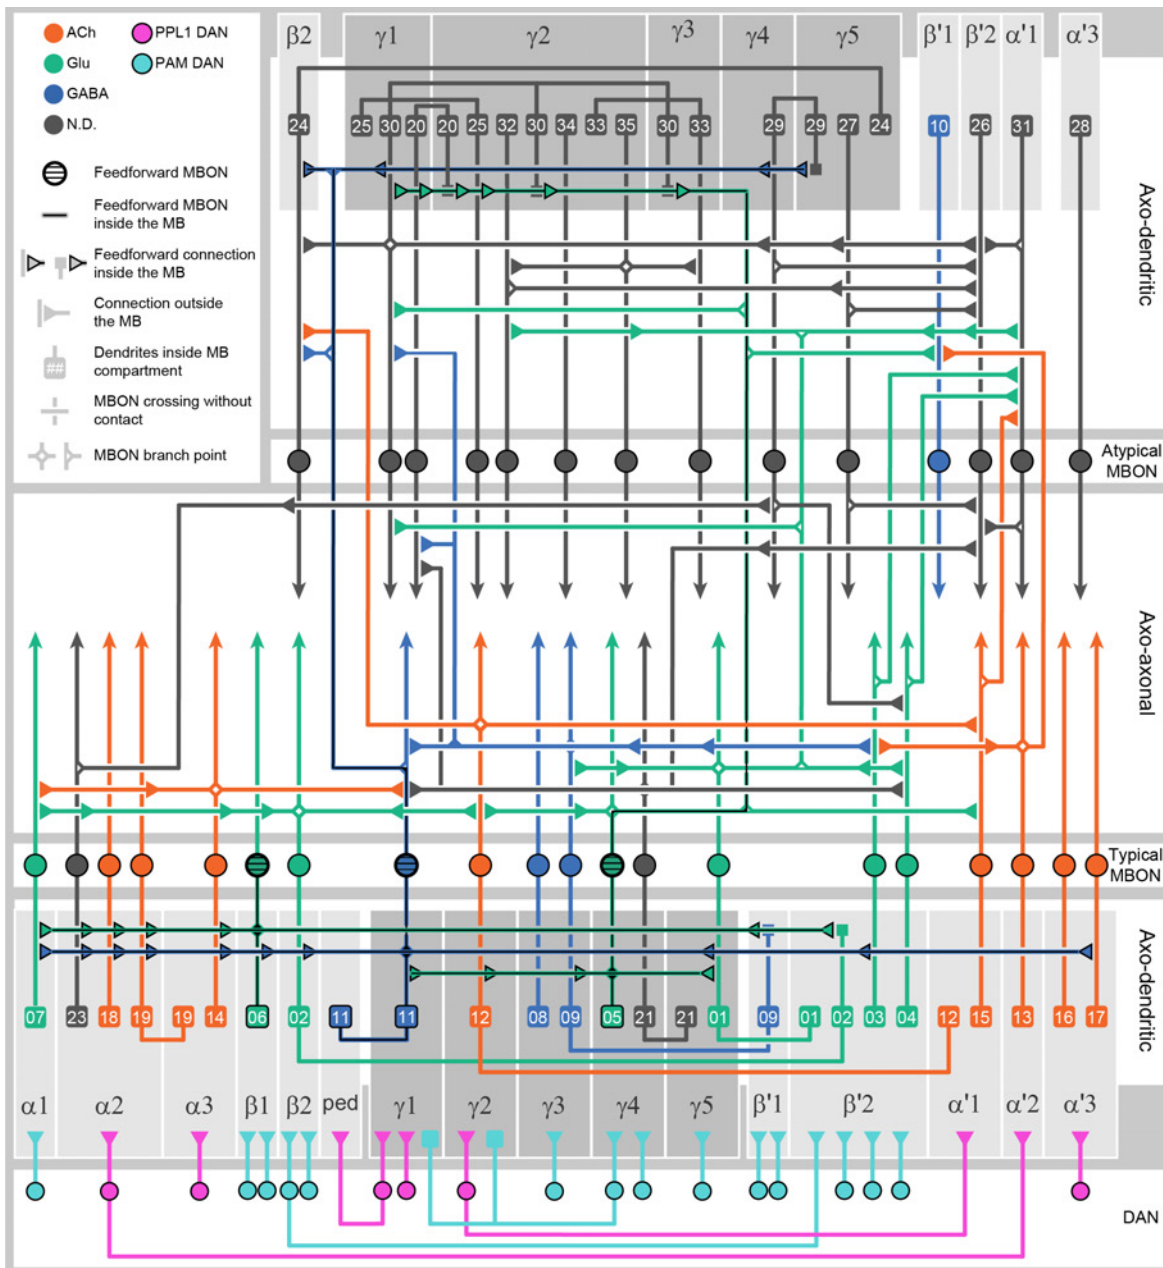

Figure 23. Diagram of the connections made between MBONs.

A diagram showing MBON to MBON connections. At the bottom, grey boxes representing each of the MB compartments and the core of the distal pedunculus (pedc). DAN inputs, with PPL1 and PAM DANs color-coded, are shown below the compartments (see Figure 6-figure supplement 1 for the names of these cell types). MBON dendrites are represented as squares that contain the identification number of the MBON cell type, color-coded by neurotransmitter; see Figure 7 for more information about these MBONs. At the top, grey boxes representing the subset of MB compartments that house the dendrites of atypical MBONs are shown; the identification numbers of the MBON cell types are given in the squares. These MBONs are described in more detail in Figure 8. Outputs from MBONs are shown outside the grey boxes, with the exception of three MBONs—MBON05 (γ 4> γ 1 γ 2), MBON06 (β 1> α) and MBON11 (γ 1pedc> α / β)—indicated by the heavier outline and striped cell bodies, send axonal terminals (triangles) back into the MB lobes. These MBONs are described in more detail in Figure 22 and Videos 23, 24 and 25. Axo-dendritic and axo-axonal connections between MBONs are diagrammed separately, as indicated.

Figure 23-figure supplement 1. Axo-axonal connections among typical MBONs outside the MB presented as a connection matrix.

This matrix shows all axo-axonal connections between pairs of typical MBONs that involve 20 or more synapses. The MBONs on the vertical axis are presynaptic to those of the horizontal axis. MBON types are sorted by neurotransmitter. Blank rows or columns are not shown. Connections are seen more frequently and are stronger between glutamatergic MBONs onto cholinergic MBONs or other glutamatergic MBONs. Likewise, GABAergic MBONs frequently synapse onto the axons of glutamatergic MBONs and MBONs with undetermined transmitter. In contrast, no axo-axonal synapses between GABAergic MBONs and cholinergic MBONs were seen in either direction. In several cases, axo-axonal synapses were highly localized and concentrated in a single axonal branch (see Figure 23-figure supplement 2).

Figure 23-figure supplement 2. Axo-axonal synapses between MBONs can be highly localized.

(A-F) Each panel shows three images: a low magnification view (upper left) of two neurons that make axo-axonal connections, a low magnification view (upper right) of just the postsynaptic neuron, and a higher resolution view of the relevant portion of its axonal arbor (lower). Neurons are color coded by neurotransmitter type. Synapses are depicted as yellow dots. (A-B) MBON01 ($\gamma 5\beta'2a$; dark green) forms axo-axonal connections onto MBON04 ($\beta'2mp_bilateral$) and MBON05 ($\gamma 4>\gamma 1\gamma 2$) with similar synapse counts, 211 and 262 respectively. (A) Synapses from MBON01 to MBON05 are widely distributed throughout MBON05's axonal terminal. (B) Synapses from MBON01 to MBON04 are highly biased towards the lateral and anterior of MBON04's axonal terminal. (C) MBON01 receives over 100 synapses from MBON09 ($\gamma 3\beta'1$)_R onto its axon. Most of these connections are localized in a smaller branch that is ventral and isolated from its main axonal arbor. (D) Localized axo-axonal connections from MBON03 ($\beta'2mp$) to MBON13 ($\alpha'2$). Note that the enlarged image has been rotated to improve visibility of the relevant arbor. (E-F) Localized axo-axonal connections between MBON03 and each of two MBON12 ($\gamma 2\alpha'1$) cells occur in the same location on the axonal arbors of [MBON12-R1](#) (E) and [MBON12-R2](#) (F).

Figure 23-figure supplement 3. Morphology of axo-axonal synapses.

(A) A portion of the MBON01 ($\gamma 5\beta'2a$) arbor from within the enlarged area shown in Figure 23-figure supplement 2C is shown in transparent green. The relative locations of axo-axonal synapses from MBON09 ($\gamma 3\beta'1$) onto MBON01 (yellow dots) and MBON01's output synapses to its downstream targets (blue dots) are indicated. (B) Electron micrograph from the hemibrain data set showing two MBON09 to MBON01 axo-axonal synapses (white arrows). Two types of vesicles are indicated by the arrowhead (small clear vesicle, white arrowhead; larger dense core vesicle, orange arrowhead). Postsynaptic densities are indicated by the hollow white arrowheads. The inset in the upper right shows a lower magnification view; MBON09 is colored brown, MBON01 is pink and annotated presynaptic sites are marked by the small green circles. (C) An axo-dendritic synapse from MBON09 to one of its downstream targets is shown for comparison. The morphologies of MBON's axo-axonal and axo-dendritic synapses are similar. (D) A portion of the MBON12 ($\gamma 2\alpha'1$) arbor from within the enlarged area shown in Figure 23-figure supplement 2F is shown in transparent green. The relative locations of axo-axonal synapses from MBON03 ($\beta'2mp$) onto MBON12 (yellow dots) and MBON12's output synapses to its downstream targets (blue dots) are indicated. (E) Electron micrograph from the hemibrain data set showing three MBON03 to MBON12 axo-axonal synapses (white arrows). Small clear vesicles are indicated by the white arrowheads. Postsynaptic densities are indicated by the hollow white arrowheads. The inset in the upper right shows a lower magnification view; MBON03 is shaded brown, MBON12 is pink. (F) An axo-dendritic synapse from MBON12 to one of its downstream targets is shown for comparison. The inset in the upper right shows a lower magnification view; MBON12 is shaded pink. The morphologies of MBON's axo-axonal and axo-dendritic synapses are similar.

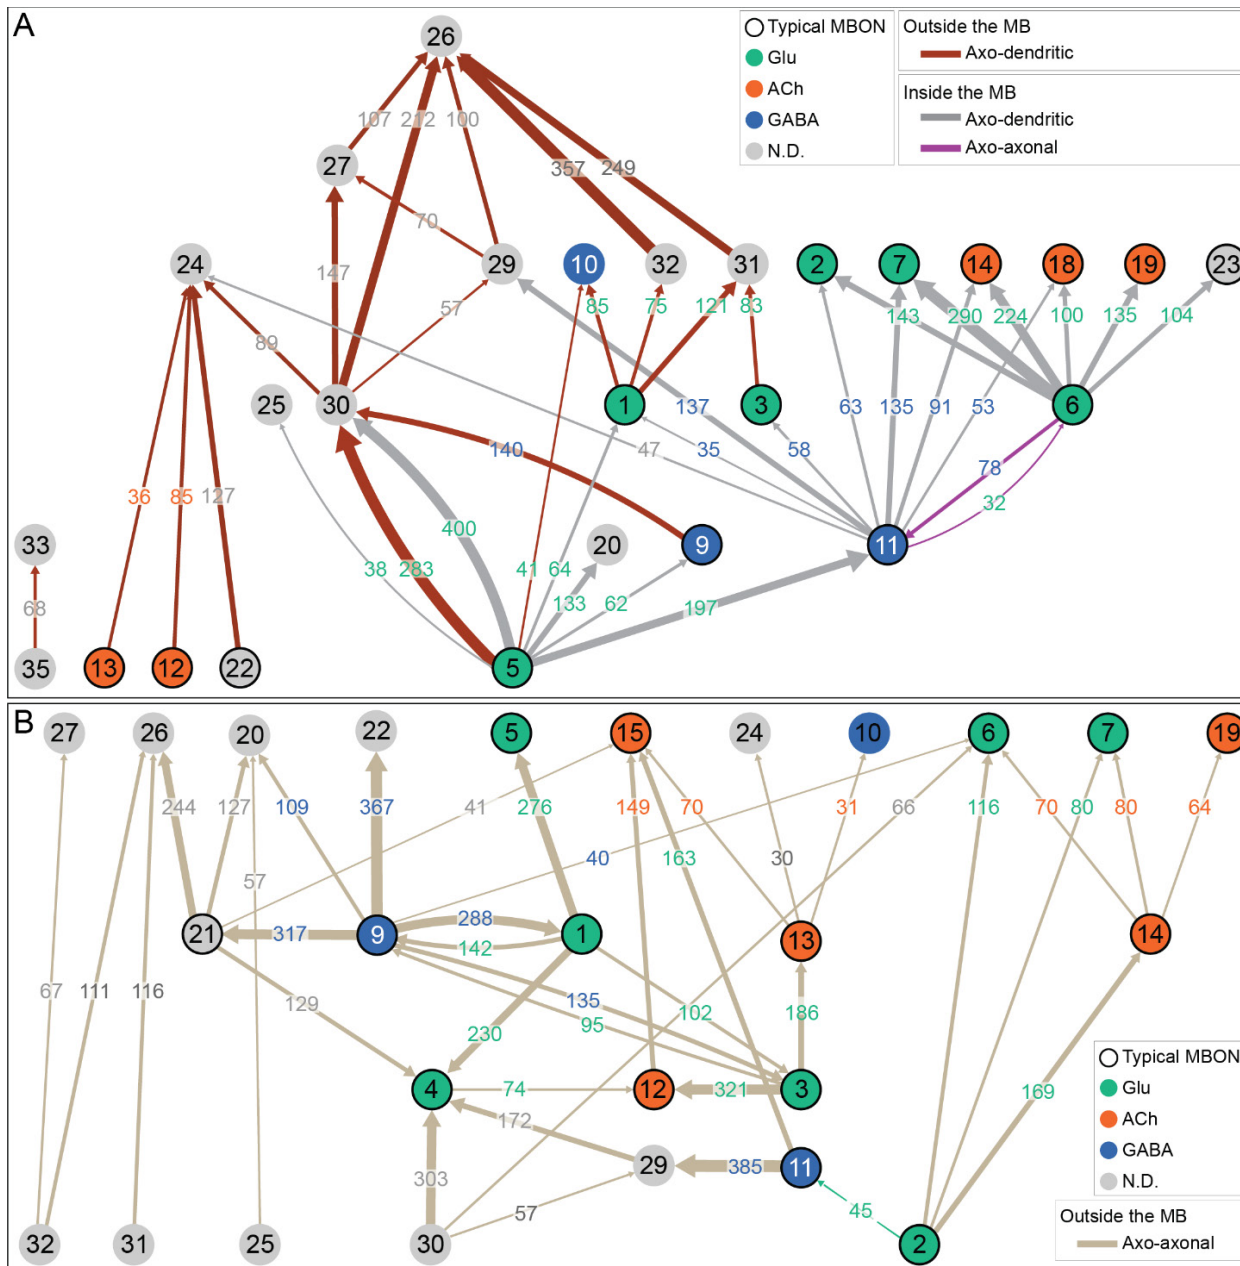

Figure 24. Connections between MBONs form a multi-layered feedforward network.

Connections between MBONs, including both typical and atypical MBONs are shown, using a threshold of 30 synapses. The color of the arrow, as indicated in the color key, represents the nature and location of the synaptic connection. The number of synapses made in any given connection is indicated by the number in the arrow and the arrow thickness is proportional to that number. Numbers have been pooled for cases where there are two MBONs of the same cell type but only connections that occur in the right hemisphere are shown. The circles representing typical MBONs are colored according to their neurotransmitter and have a black border; atypical MBONs are shown without a border and in grey except for the atypical MBON10 that is GABAergic. (A) Axo-dendritic connections outside the MB lobes, axo-dendritic connections inside the MB lobes provided by feedforward MBONs (MBON05, MBON06 and MBON11), and the reciprocal axo-axonal connections between MBON6 and MBON11 within the MB lobes. (B) Axo-axonal synapses outside the MB lobes. Note that some MBONs, such as MBON26, form both axo-dendritic and axo-axonal connections outside the MB (see Figure 8-figure supplement 5E).

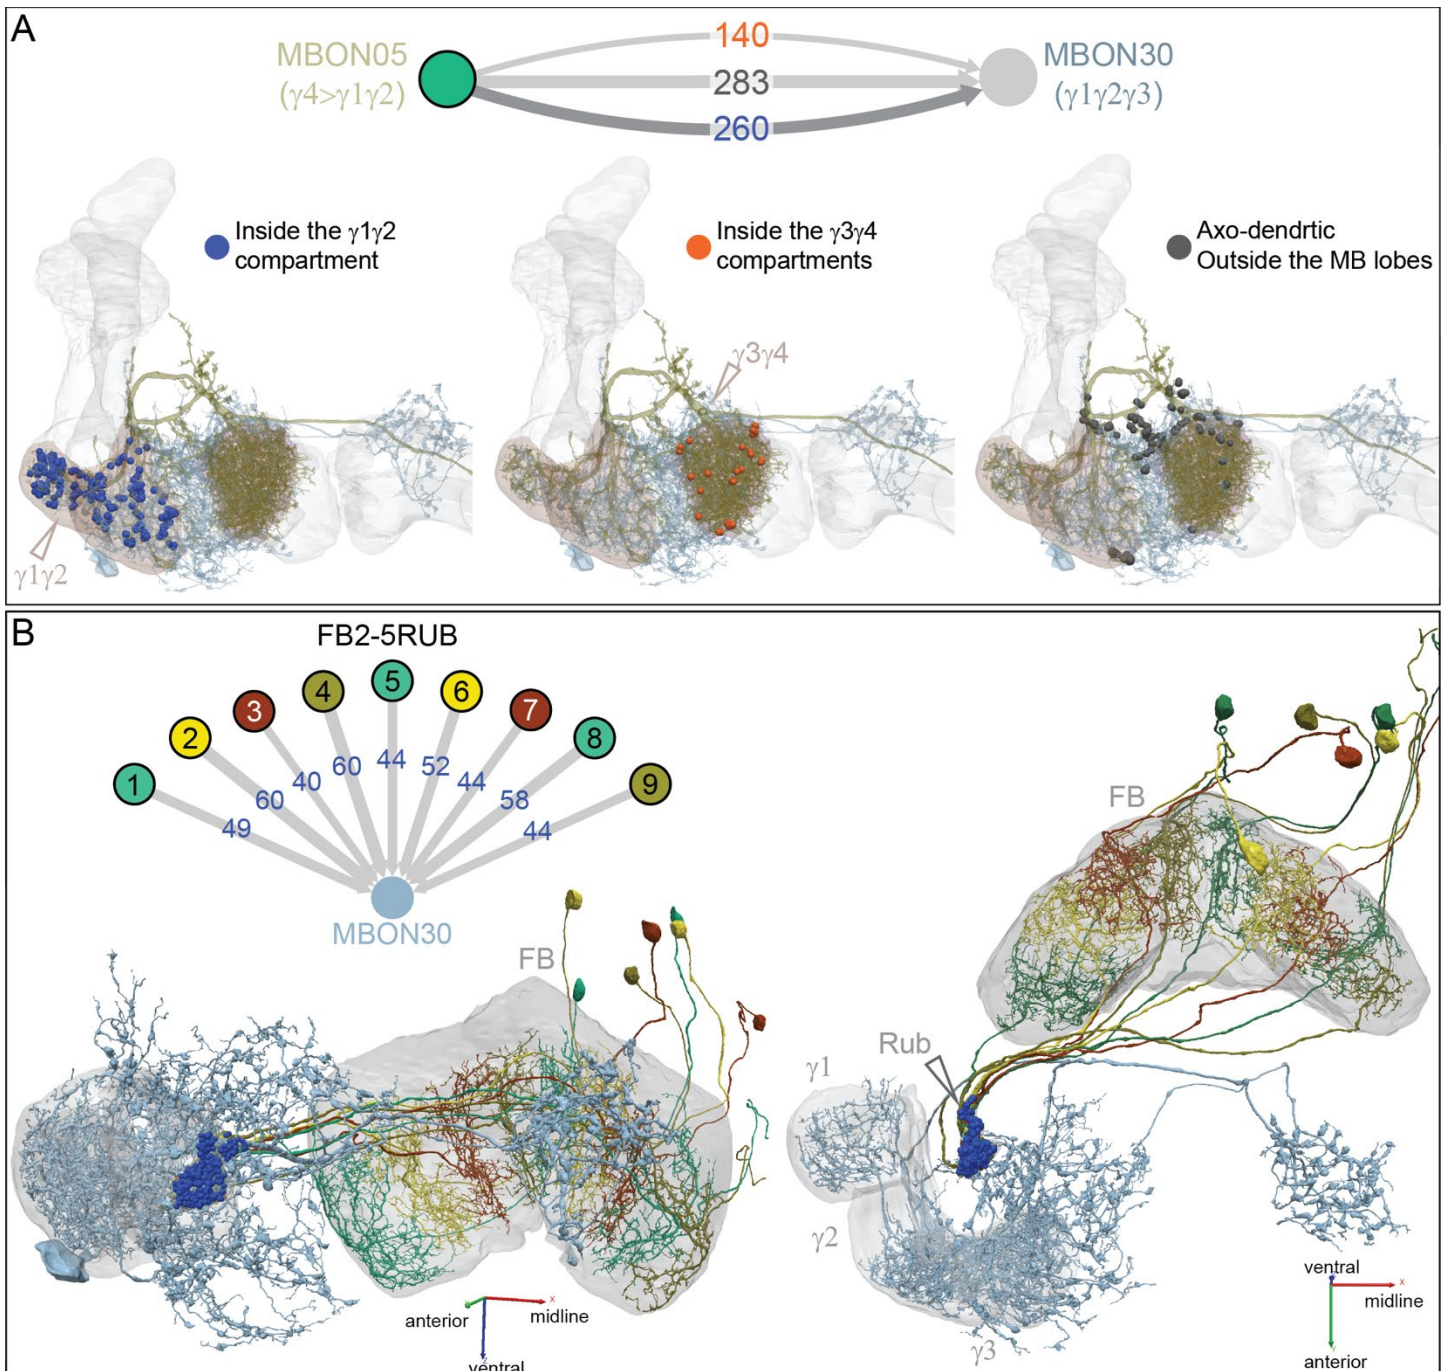

Figure 24-figure supplement 1. MBON30 displays an unusual pattern of innervation from other MBONs and FB neurons. (A) MBON30 receives strong input from MBON05, a feedforward glutamatergic MBON, through three distinct axo-dendritic paths: inside the γ_1 and γ_2 compartments (260 synapses); inside the γ_3 and γ_4 compartments (140 synapses); and outside the MB lobes (283 synapses). The locations of synapses used in each of these three connections are shown. Note that in the connectivity diagram in Figure 24, the arrow represents all 400 synapses that occur in either the γ_1 and γ_2 compartments (260) or in the γ_3 and γ_4 compartments (140). (B) MBON30 receives strong input from the FB mediated by the FB2-5RUB cell type which has nine columnar cells. The connection occurs inside the RUB. MBON30 is the only MBON that has input from an FB cell type among its top 10 inputs.

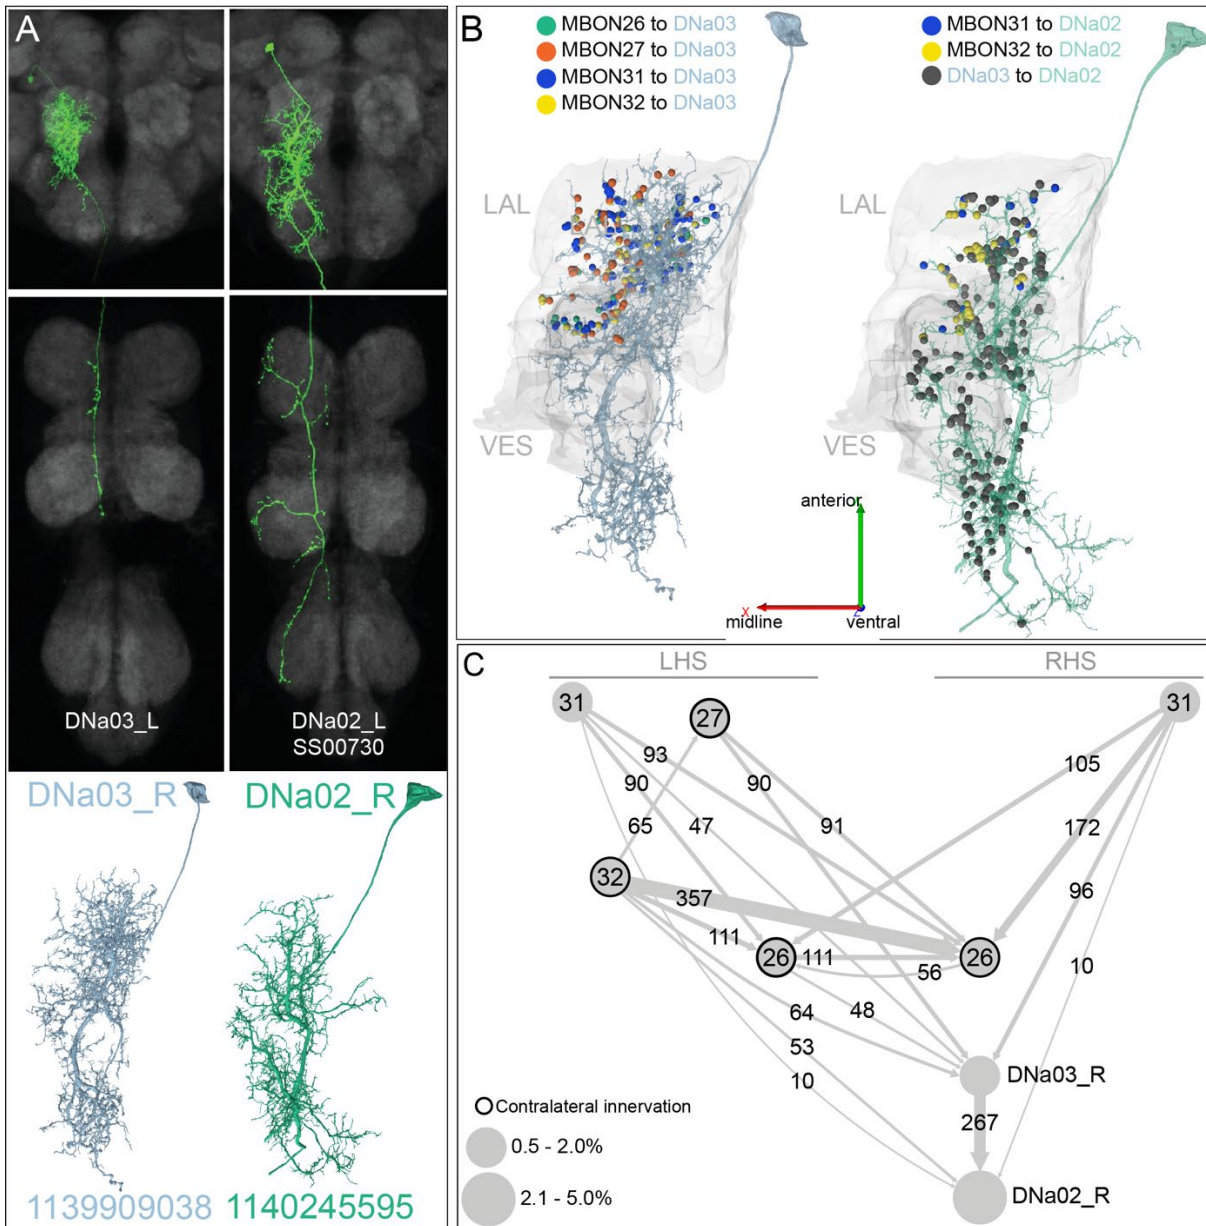

Figure 25. A descending pathway from atypical MBONs to the ventral nerve cord (VNC).

Four LAL-innervating atypical MBONs form strong connections to descending neurons (DN). (A) A comparison between LM (Namiki et al., 2018) and EM morphologies of **DNa02** and **DNa03**. Note that the LM images show the cells in the left hemisphere while the EM images are from the right hemisphere and that the axons of the DNs extend outside the hemibrain volume. (B) Synaptic connections from MBON26, MBON27, MBON31 and MBON32 to DNa03 (left) and from MBON31, MBON32 and DNa03 to DNa02 (right) are shown, color coded. Note the connections from MBONs are restricted to the LAL while DNa03 makes synapses onto DNa02 throughout its arbor in the LAL and the VES. (C) Diagram of connectivity between MBONs, DNa03 and DNa02. Note that MBON26, MBON27 and MBON32 have contralateral axons (Figure 8-figure supplements 5, 6 and 11, Video 11, 12 and 17) and thus innervate the contralateral DNa02 and DNa03 while MBON31 has bilateral output (Figure 8-figure supplement 10, Video 16). Thus the connectivity diagram shows the inputs onto the DNa02 and DNa03 of the right hemisphere (RHS), while many of the neurons providing input have their cell bodies in the left hemisphere (LHS). Other inputs to DNa02 and DNa03 are summarized in Figure 25-figure supplement 1. DNa02 has been implicated in steering control (Rayshubskiy et al., 2020).

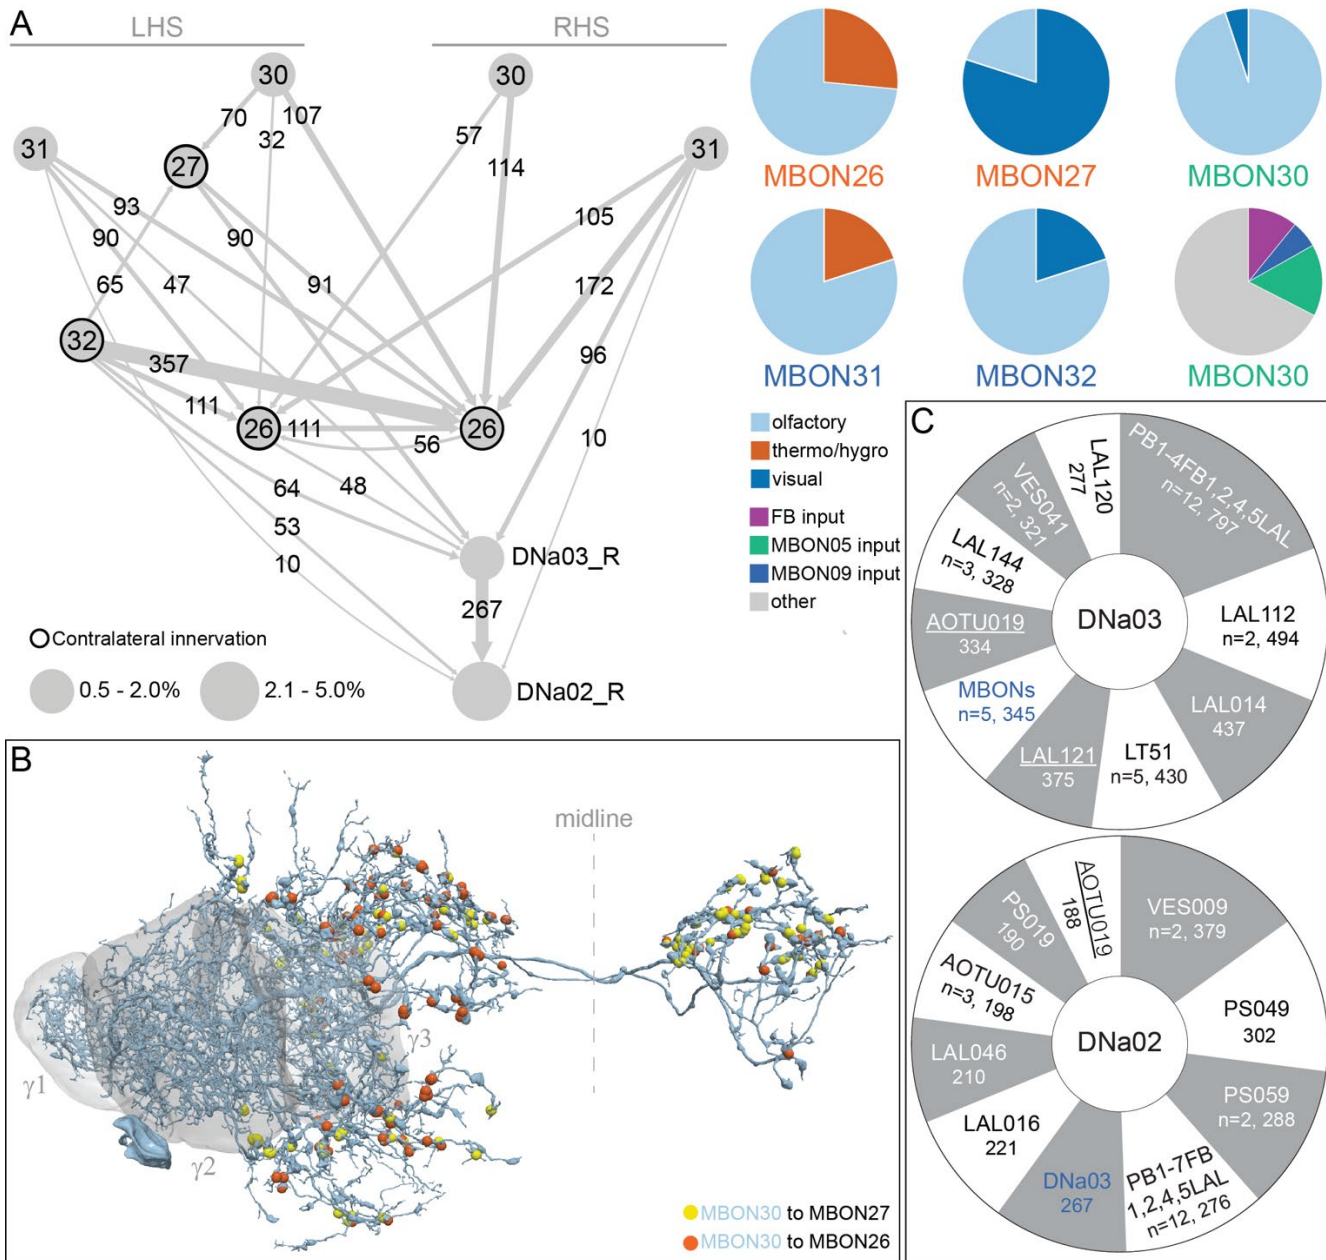

Figure 25-figure supplement 1. Top inputs to DNα02 and DNα03

(A) Left: Expanded connectivity diagram now including MBON30. MBON30 provides strong input to MBON26 and MBON27 (Figure 24) and conveys information from the FB (Figure 24-figure supplement 1; Video 15). Right: Pie charts describing inputs to MBON26, MBON27, MBON30, MBON31 and MBON32. The first five pie charts show the modalities of sensory information conveyed to these MBONs by KCs (data taken from Figure 15-supplement 2). Note MBON26 and MBON31 receive substantial thermo/hygro sensory input and MBON 27 and MBON32 receive substantial visual input. MBON30 receives strong input from MBON05 and MBON09, as well as from a single FB columnar neuron cell type (FB2-5RUB); these three cell types provide 36 percent of MBON30's input, when input from KCs, DANs, APL and DPM is excluded. (B) The presynaptic sites on MBON30 that connect to MBON26 and MBON27 are shown, color coded. (C) Sunburst charts showing the ten cell types providing the largest amount of input, based on synapse number, to DNα03 (top) and DNα02 (bottom). The number of synapses and the number of cells in the cell type if more than one (n=) are shown. Neuron names with underscore indicate they innervate the contralateral side.

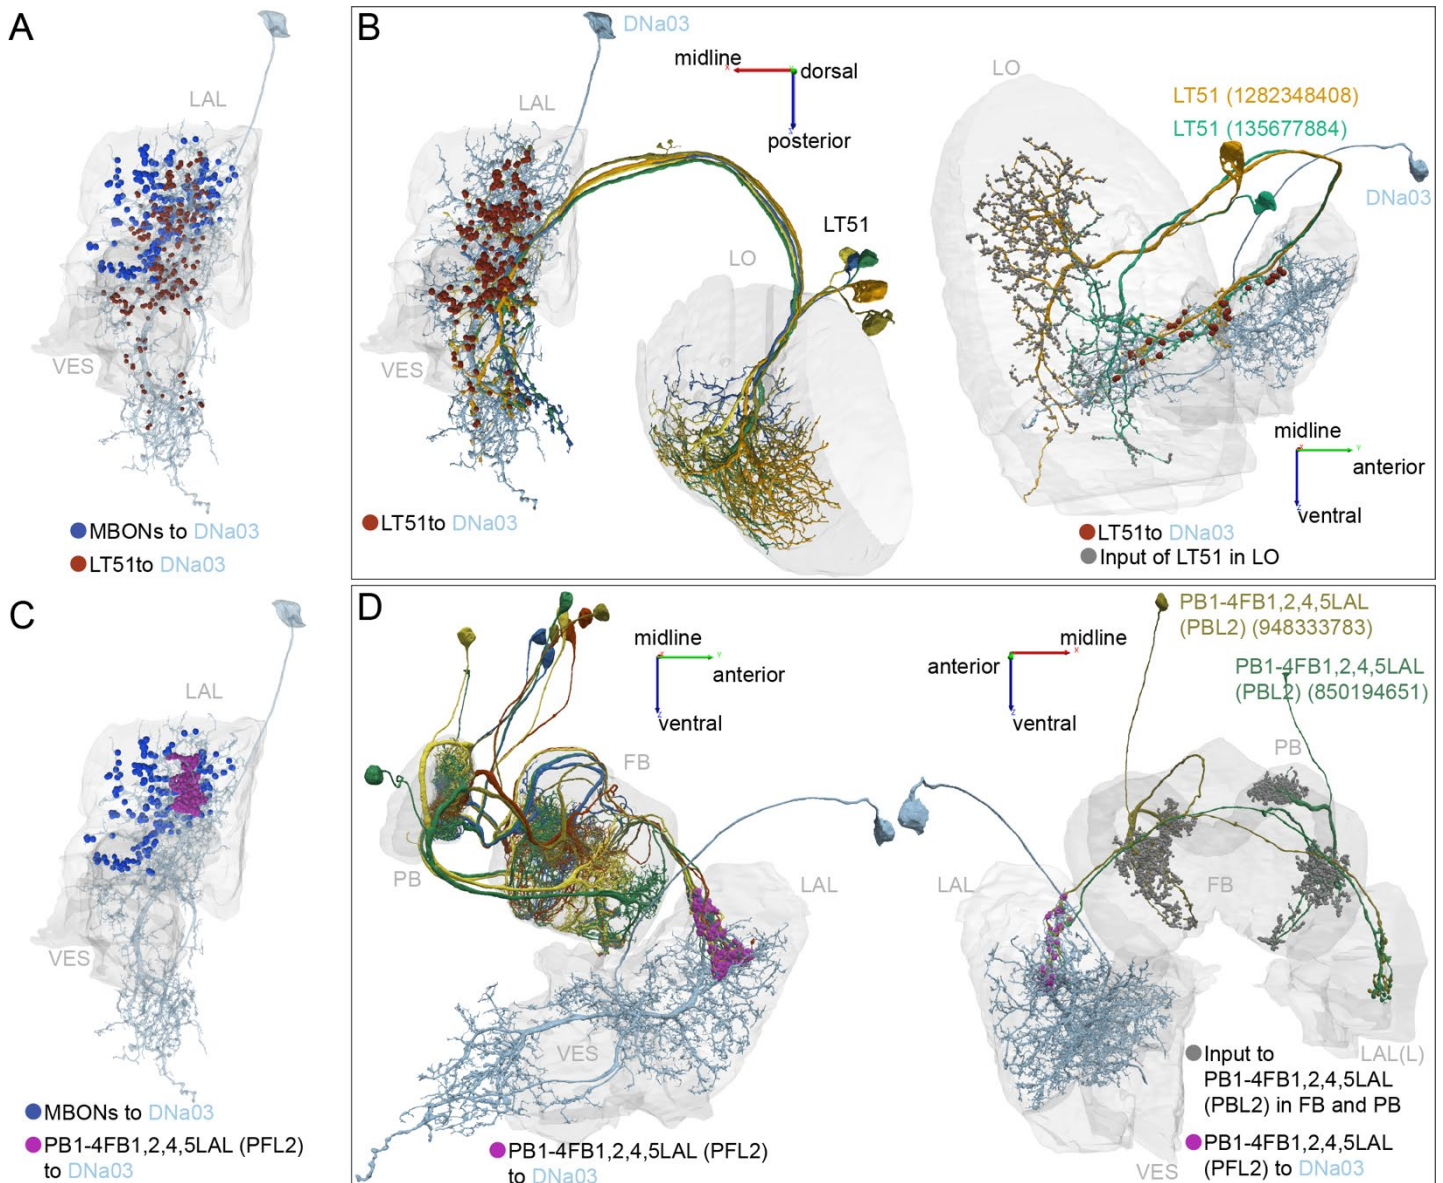

Figure 25-figure supplement 2. Central complex and LO inputs to DNa03.

(A) DNa03 receives strong visual input from lobula tangential (LT) neurons, LT51 (also see Figure 25-figure supplement 1 C). The five LT51 neurons make 430 synapses onto DNa03, shown as reddish brown dots. These connections are located at the core of the DNa03 dendrite while the MBONs synapse onto DNa03 around the periphery (shown as blue dots). The five LT51s that synapse onto DNa03 represent only a subset of the twelve LT51 identified in the right optic lobe and the two of these cells account for 362 of the 430 synapses from LT51 cells to DNa03. Interestingly, these five connected LT51 cells have their dendrites in the same half of the lobula, corresponding to the frontal part of the visual field. (B) Left: a dorsal view of LT51 connecting to DNa03. Right: two LT51 neurons connecting to DNa03 are shown with their postsynaptic sites in the LO indicated by the grey dots and presynaptic connections to DNa03 as reddish brown dots. (C) The strongest input cell type to DNa03 is a cell type with dendrites in the PB and the FB, PB1-4FB1,2,4,5LAL (PFL2), with 12 such cells making a total of ~800 synapses (also see Figure 25-figure supplement 1 C). These synaptic connections are highly concentrated on a small dendritic area of DNa03, shown in purple with MBON input on the periphery (blue). (D) Left: Side view of the connections between the PFL2 neurons and DNa03. Right: Two of the PFL2 neurons are shown with their output to DNa03 (purple) and their input sites in FB and PB (grey). Note that PFL2 neurons are highly polarized.

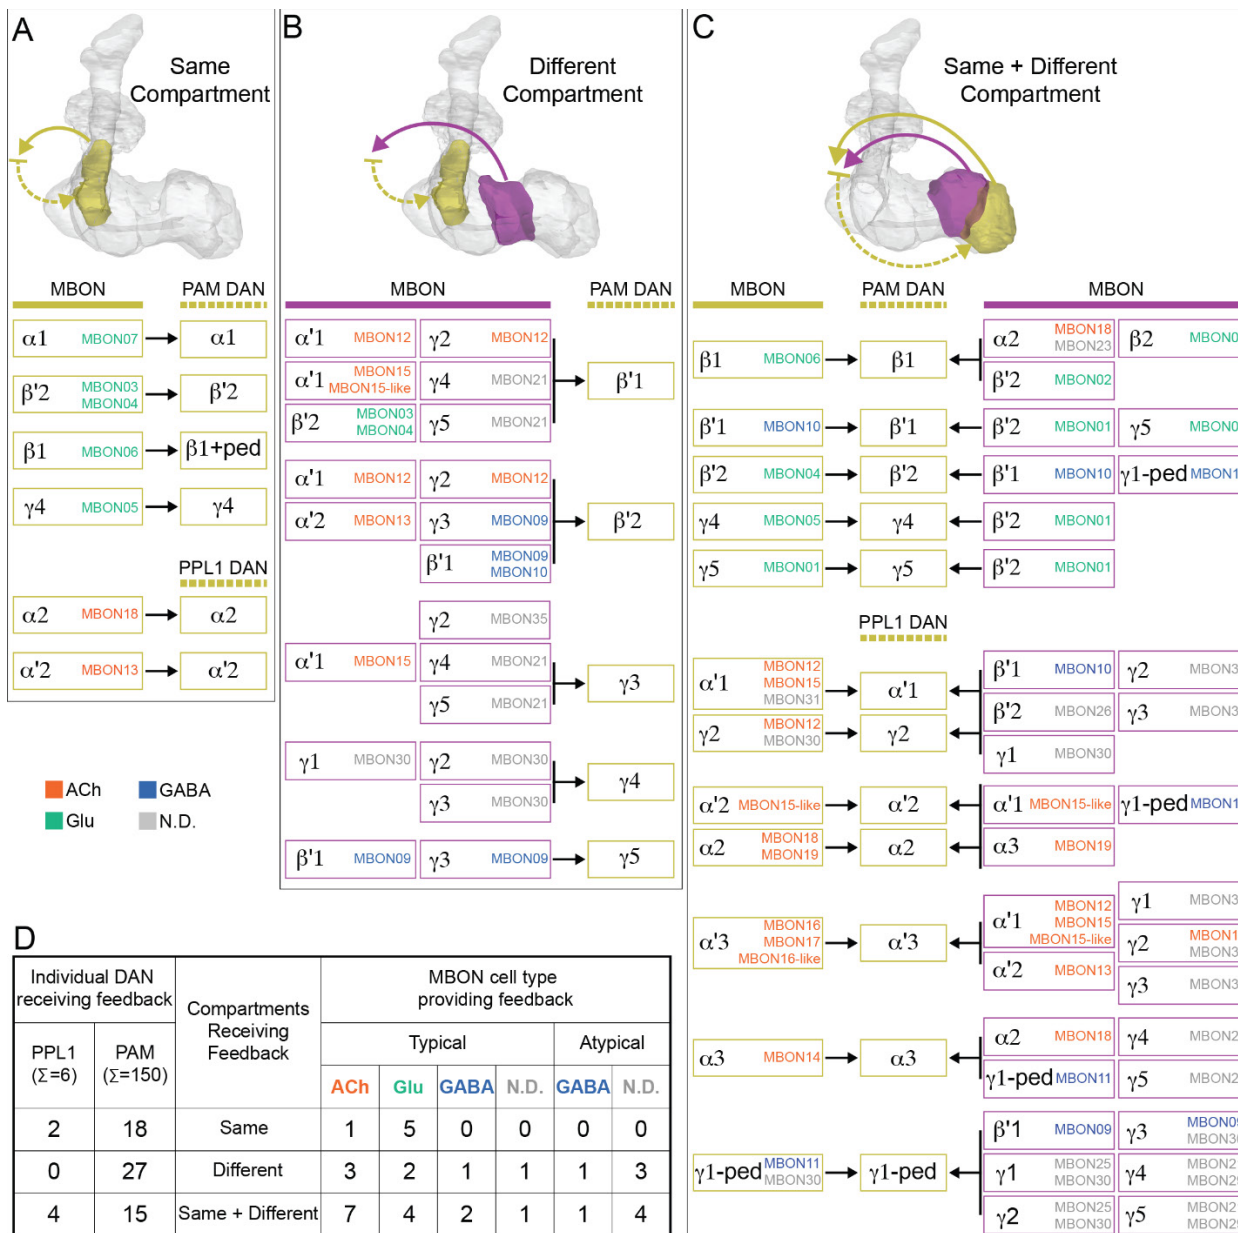

Figure 26. Feedback from MBONs to DANs.

Input from MBONs onto DANs occurs in three distinct circuit motifs which are diagrammed. MBON connections to DANs from the same compartment are depicted as a yellow arrow, while MBON connections to DANs from a different compartment are depicted as a purple arrow. DANs downstream of these MBONs are depicted as dashed yellow arrows. (A) In the simplest case, the MBON and DAN form a reciprocal loop where the MBON innervates DAN(s) that send their axons back to the compartment where the MBON's dendrites arborize. Below the diagram of this circuit motif, each of the instances we observed with this arrangement is presented; inputs onto PAM and PPL1 DANs are presented separately. The color of the MBON name indicates its neurotransmitter, when known. (B) In this case, MBON(s) synapse onto DAN(s) that send their axons to different MB compartment(s), providing a mechanism for cross-compartment communication. It is common for DANs to receive input from several MBONs. (C) This motif combines the previous two motifs, with DANs receiving input from both MBON(s) of same and different compartments. (D) The table summarizes DAN populations that participate in the three different feedback motifs. Note that all 6 PPL1 DANs receive MBON input, but only a subset of the 151 PAM DANs receives MBON input.

Figure 26-figure supplement 1. MBON to DAN feedback mediated by an interneuron.

MBONs also make indirect connections to DANs in which the MBON connects to an interneuron which then connects to a DAN. This matrix shows the effective connection strength of such MBON-to-DAN feedback loops and is meant to complement the data presented in Figure 26, which describes direct connections between MBONs and DANs. Effective connection strength is a measure that takes into account both the strength of the MBON's connection to the interneuron and that of the interneuron to the DAN. Effective connection strength is computed by multiplying the matrix of DAN inputs with the matrix of MBON outputs (both matrices are normalized so that the inputs to each neuron sum to 1). This connection strength is averaged across all DANs of the indicated type. Highlighted boxes indicate interactions between MBONs and DANs that share a compartment, and the box color indicates the neurotransmitter of the MBON. MBONs are ordered by their proportion of self-feedback, as defined and shown in Figure 26-figure supplement 2.

Figure 26-figure supplement 2. Distribution of DAN feedback mediated by an interneuron.

This plot shows the ratio of feedback to the same compartment (self-feedback) to feedback to other compartments (other-feedback) for each MBON type; color-coding indicates the neurotransmitter used by the MBON. The plot reveals a robust pattern of glutamatergic (and to a lesser extent, cholinergic) MBONs indirectly modulating their associated DANs. The plot is meant to complement the data presented in Figure 26, which describes direct connections between MBONs and DANs. The strength of indirect self-feedback is defined as the average effective connection strength mediated by one interneuron between a given MBON and the DANs that innervate the same compartment. The strength of average other-feedback is defined as the average effective connection strength between the MBON and all other DANs, again mediated by one interneuron. The value plotted on the y-axis is the ratio of these two quantities. That is, MBONs with higher ratios have a larger fraction of the interneuron-mediated feedback they initiate directed back to their own compartment, rather than to other compartments.

Figure 27. Similarity of input to individual DANs.

Heatmap representing the similarity of inputs received by DANs. Each square represents the cosine similarity of inputs received by each PAM or PPL1 DAN. In order to focus on inputs received outside the lobes of the MB, inputs from KCs, other DANs, APL and DPM neurons have been excluded. DANs are grouped by type, and the ordering within each type is determined by spectral clustering. Colors on the diagonal indicate whether the given DAN receives feedback from MBONs in the same compartment (yellow), MBONs from different compartments (purple), both (green), or neither (dark blue). Figure 27-figure supplement 1 shows an expanded view of the PPL1 DAN portion of the heatmap. Figure 27-figure supplement 2 shows the average input similarity between DAN cell types computed after pooling the data for all cells of a given DAN cell type.

Figure 27-figure supplement 1. Similarity of inputs to PPL1 DANs.

Expanded view of Figure 27 for PPL1 DANs (red square in Figure 27). Note that each PPL1 DAN receives direct feedback from MBONs, including the MBON from its own compartment. Colors on the diagonal indicate whether the given DAN receives feedback from MBONs in the same compartment (yellow) or from both the same and different compartments (green).

Figure 27-figure supplement 2. Similarity of inputs to DAN cell types.

Average input similarity between DAN cell types computed after pooling the data for all cells of a given type, as compared to Figure 27 where each individual DAN is plotted separately.

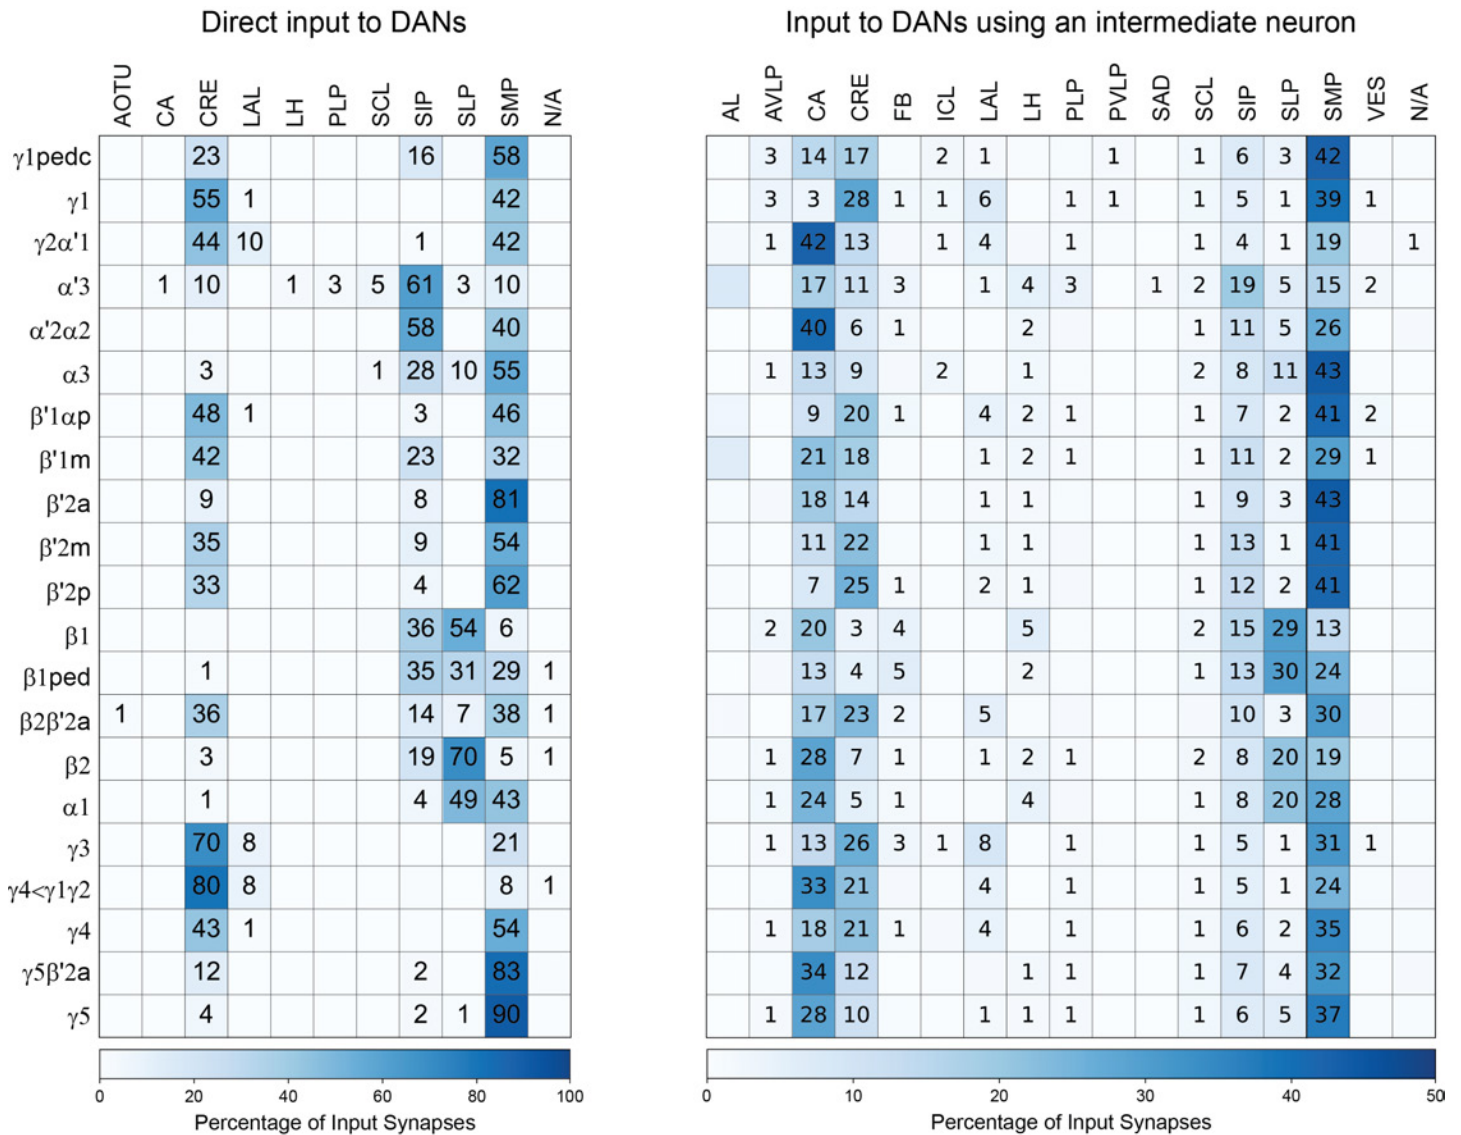

Figure 27-figure supplement 3. DAN input distribution by brain region.

(Left) The value in each box indicates the percentage of the given DAN type's input synapses that lie in the given brain region. Blank boxes indicate values of less than 1%. (Right) Distribution of brain regions providing input to DAN types using an intermediate interneuron. The value in each box indicates the effective input to the given DAN from the given brain region, mediated by one interneuron. Effective input is a measure that takes into account both the strength of the connection of each of the neurons that provide input to the DAN and the connection strength of other neurons to each of those input interneurons in each brain region. Effective input is computed by matrix-multiplying the inputs to the DANs and the inputs to those DAN-presynaptic neurons (normalizing both matrices so that inputs to all neurons sum to 1). Blank boxes indicate values of less than 1%. The two distributions are generally similar, but there are some clear differences. For example, direct input from CA is minimal but very prominent in input mediated by an interneuron; for example, the $\gamma 2\alpha'1$ PPL103 DAN receives over 40% of its indirect input from the CA.

Figure 27-figure supplement 4. Comparing DAN inputs and MBON outputs reveals credit assignment by DANs. Scatter plot of DAN input similarity (data from Figure 27) and MBON output similarity (data from Figure 16, collapsed by compartment). Each point represents a pair of compartments; notable pairs are labeled in the figure. DAN input similarity is defined as the cosine similarity of the inputs to the DANs of two compartments. MBON output similarity measures the cosine similarity of the outputs from the MBONs in those compartments. The relationship between the two similarity measures indicates that compartments whose MBONs project to similar downstream targets have DANs that receive similar inputs. This structure suggests a form of “credit assignment” in which compartments whose MBONs control similar behaviors also receive similar reinforcement signals. Results are shown for compartments whose MBONs express excitatory (top, ACh) or putatively inhibitory (bottom, GABA and Glu) neurotransmitters.

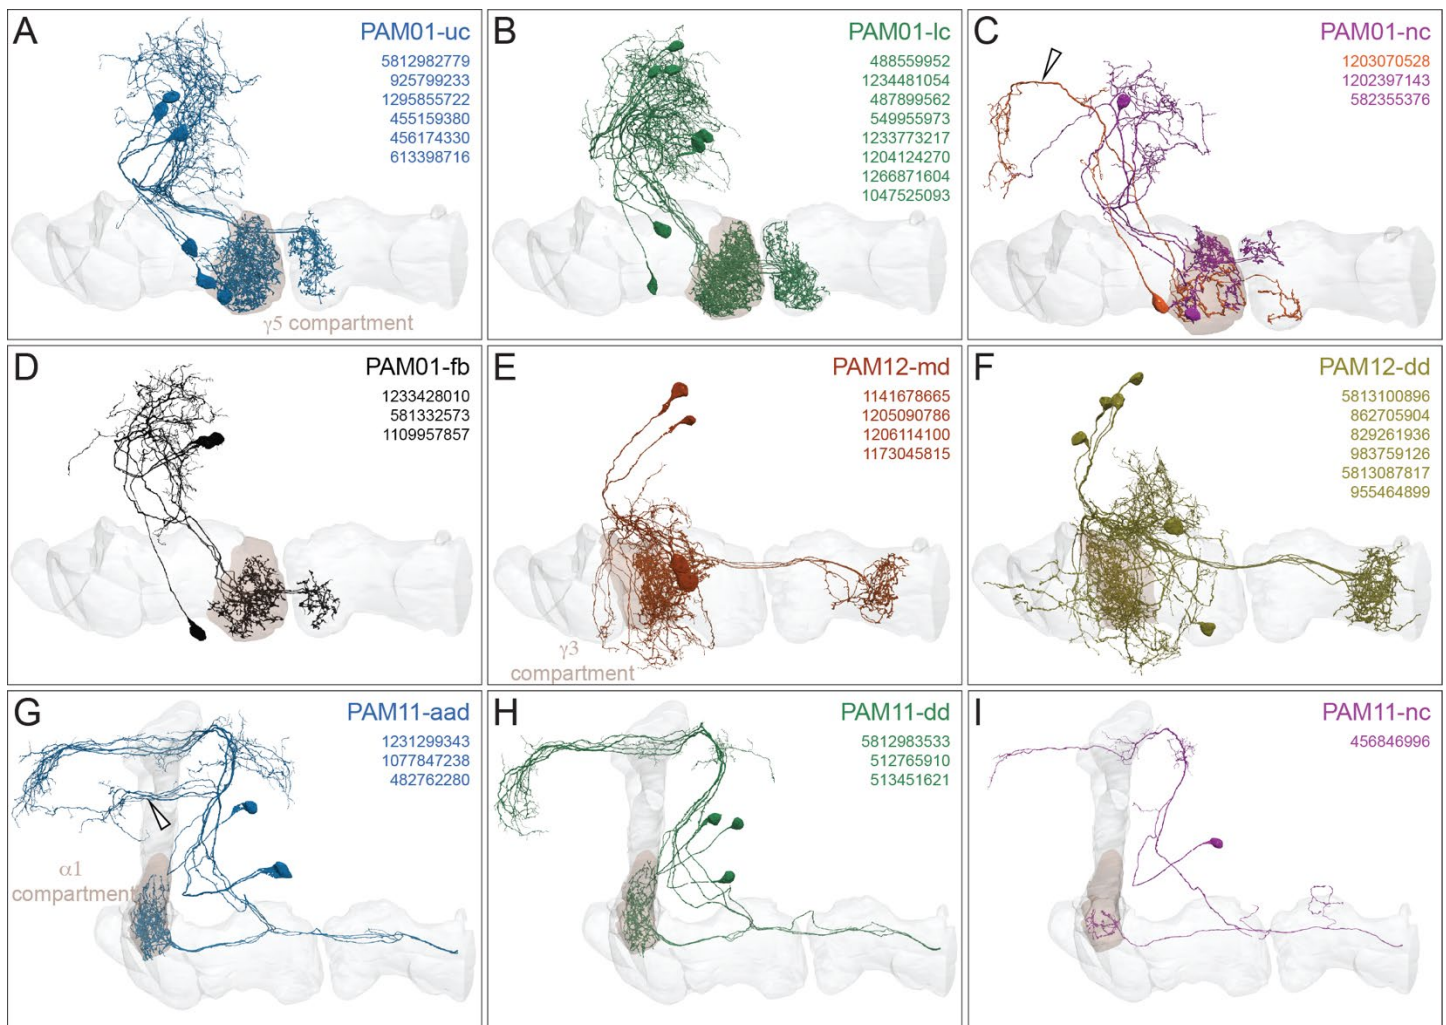

Figure 28-figure supplement 1. Anatomy of PAM01, PAM12, and PAM11 DAN subtypes.

Morphologies of DAN subtypes discussed in Figure 28. Innervated MB lobes are shown in grey and the relevant compartment in brown. (A) Six PAM01-uc DANs (blue) project across the upper commissure (uc). (B) Eight PAM01-lc DANs (green) project across the lower commissure (lc). The dendritic field of PAM01-lc also extends slightly more anterior and ventral compared to PAM01-uc DANs (A). (C) Three non-canonical (nc) PAM01-nc DANs (magenta and orange) shown together. A single [PAM01-nc](#) DAN (orange, crossing the lc) has an additional dendritic branch in the SLP (indicated by arrowhead) and two other [PAM01-nc](#) DANs (1202397143, 582355376, crossing the uc) have axons confined to the dorsal or lateral portion of the $\gamma 5$ compartment. (D) Three [PAM01-fb](#) DANs receive direct feedback (fb) from MBON01 ($\gamma 5\beta^2\alpha$) and their presynaptic fields are confined to the ventral portion of the $\gamma 5$ compartment, in contrast to other PAM01 DANs. They also project through the lower commissure. Subtypes match those in Otto et al. 2020. (E-F) PAM12 DANs divide into (E) four medial dendrite (md) [PAM12-md](#) DANs (maroon) and (F) six dorsal dendrite (dd) [PAM12-dd](#) DANs (ochre) (also see Figure 33). (G-I) The three morphological groups of PAM11 DANs. These DANs are also shown in Video 32. (G) Three [PAM11-aad](#) DANs (blue) have an additional anterior dendrite (aad) anterior to the $\alpha 1$ lobe (arrowhead). (H) Three dorsal dendrite (dd) [PAM11-dd](#) DANs (green). (I) One non-canonical (nc) [PAM11-nc](#) DAN (magenta), which unlike the other PAM11 DANs, has an axonal field confined to the middle of the $\alpha 1$ compartment.

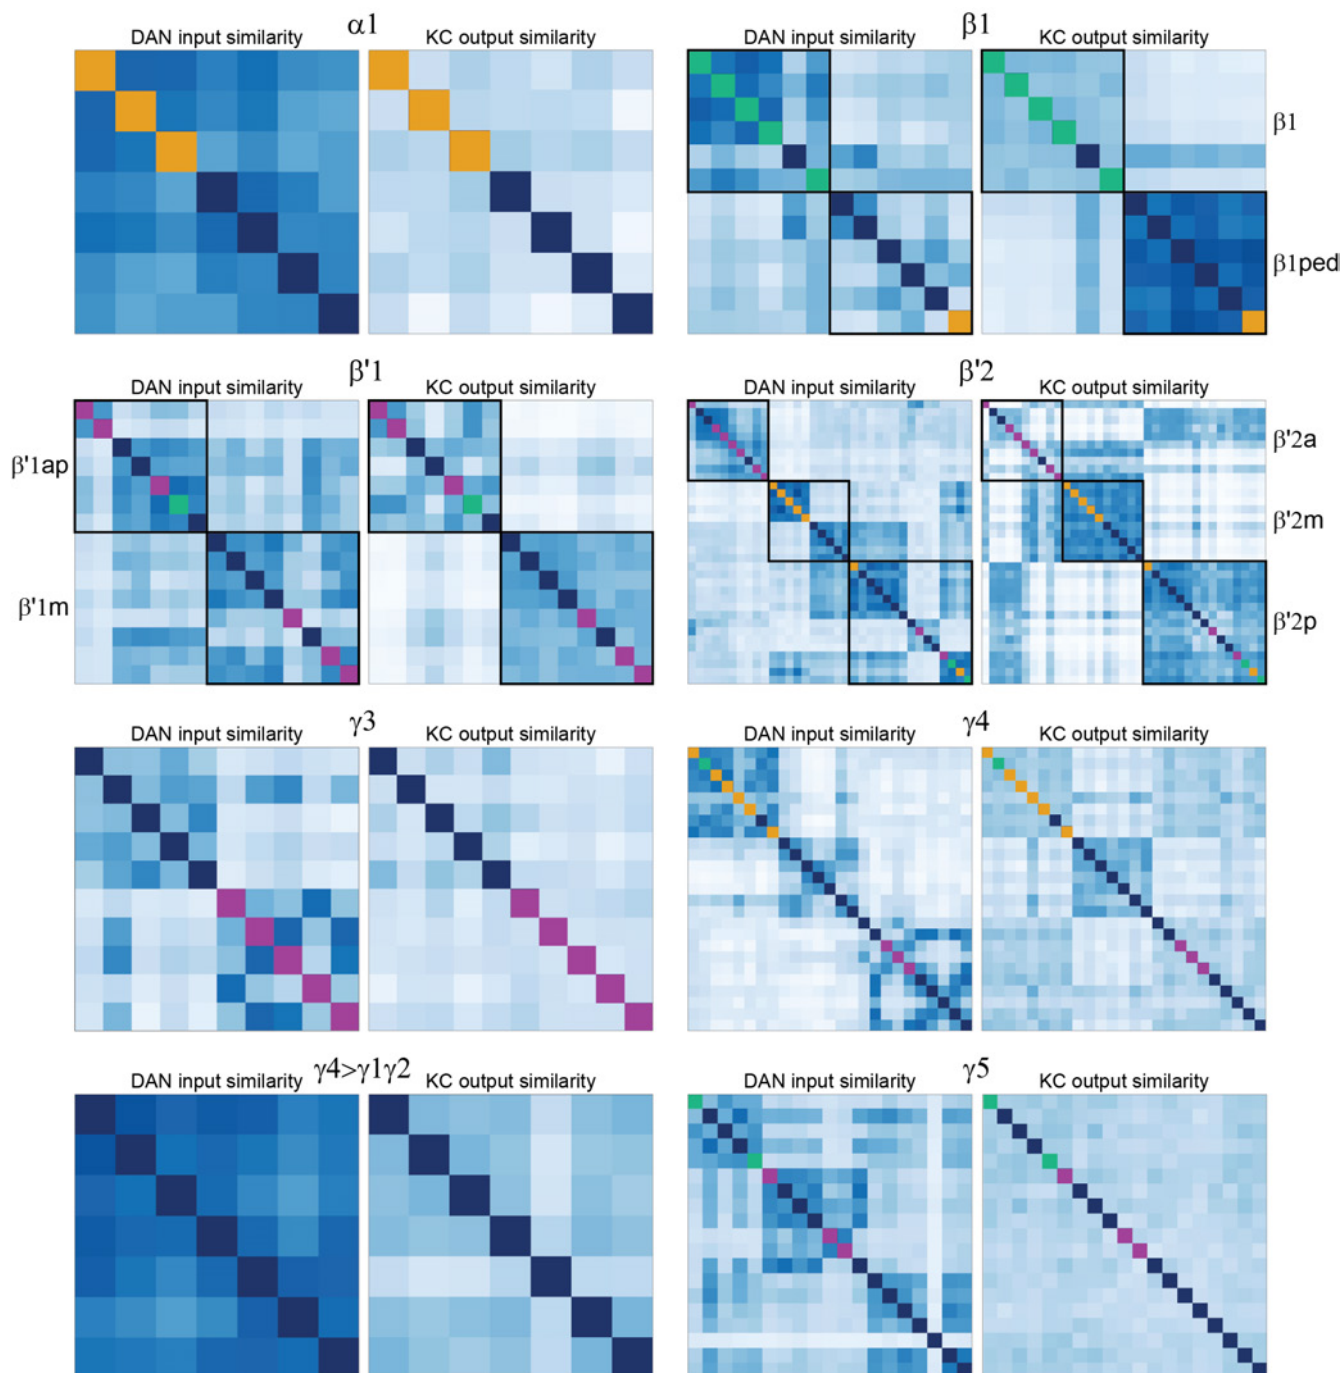

Figure 29. Relationship between DAN dendritic inputs and DAN axonal outputs to KCs.

These plots explore whether DANs of the same cell type that have distinct inputs also connect to distinct populations of KCs within a compartment. Analysis of eight compartments is shown. Within each example, the left heatmap represents the similarity of input to DANs (identical to the corresponding block in Figure 27). The right heatmap represents the cosine similarity of the output synapses made by DANs onto KCs. The clustering observed in the right panels most likely results from individual PAM neurons only arborizing in a portion of their compartment (see neuronal morphologies Figure 28-figure supplement 1 and Figure 30). Such clustering may permit specific reinforcement signals to be conveyed to subsets of KCs within a compartment. See detailed discussion of DAN-KC connectivity in Figure 30 and Figure 30-figure supplements 1 and 2. The potential computational significance of this phenomenon is explored in Figure 38.

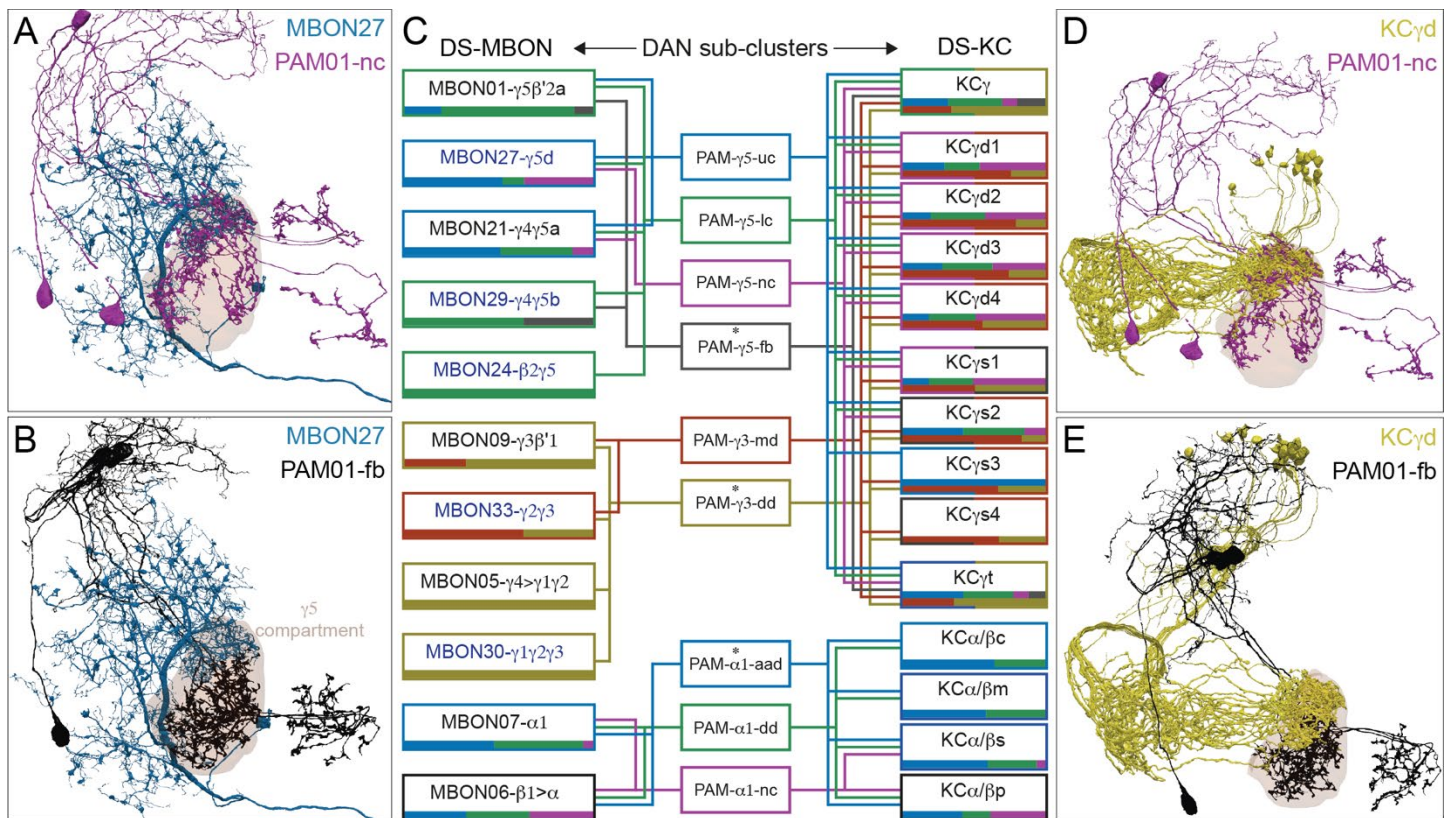

Figure 30. Different subtypes of the PAM01, PAM12, and PAM11 DANs synapse onto specific subpopulations of KCs and MBONs within their compartment.

The axons from certain subtypes of DAN occupy different regions of, and together tile, a MB compartment. This permits for specific connectivity to KCs and MBONs within the compartment. A zonal subcompartment arrangement is a feature of many MB compartments and is illustrated here by the distinct morphologies of two subtypes of the $\gamma 5$ compartment DANs (A, B, D, E). Implications for connectivity of this type of restricted DAN arborization are summarized for the $\gamma 5$, $\gamma 3$, and $\alpha 1$ compartments in panel C. Figure 30-figure supplements 2 and 3 show connectivity matrices for additional compartments in the right hemisphere. (A) The axons from PAM01-nc (magenta) overlap with dendrites of MBON27 ($\gamma 5d$; dark blue). Note that the axons of the two PAM01-nc DANs (magenta) are confined to the dorsal and lateral region of the $\gamma 5$ compartment (see also Figure 28-figure supplement 1C). (B) PAM01-fb (black) axons do not overlap with the dendrites of MBON27 (dark blue). (C) Schematic of the innervation of subtypes of $\gamma 5$, $\gamma 3$, and $\alpha 1$ DANs within the compartment showing their connection to MBONs (left) and KCs (right). Boxes for DAN subtypes and connectivity edges are colored according to subtype identity. Boxes around MBON types are colored by their strongest DAN subtype input. The boxes around KC names are colored to reflect their strongest DAN subtype input in each compartment (the two halves for KC γ types reflect their projections through the $\gamma 3$ and $\gamma 5$ compartments). Horizontal bars along the lower edge of the MBON and KC boxes are histograms, with bar colors corresponding to DAN subtypes, representing the proportion of each DAN subtype providing input to the respective MBON or KC subtype. For the KC γ types, the upper bar represents inputs in $\gamma 5$ and the lower bar in $\gamma 3$. Typical MBON names in black and atypical MBONs are in blue. Asterisks denote DAN subtypes receiving MBON feedback (compare with Figures 26, 27 and 28). Only cases where a DAN provides at least 0.1% of the MBON's synaptic input or at least 1% of a KC type's input from DANs are shown. KC cell types are biased in their representation of different sensory modalities (Figure 15-figure supplement 2). Note that the synapses onto the feedforward MBON06 ($\beta 1>\alpha$) are likely axo-axonal. (D) The axons from PAM01-nc (magenta) also overlap with the axonal processes of KC γd (yellow). (E) Axons from PAM01-fb (black) do not overlap with the axonal processes of KC γd (yellow).

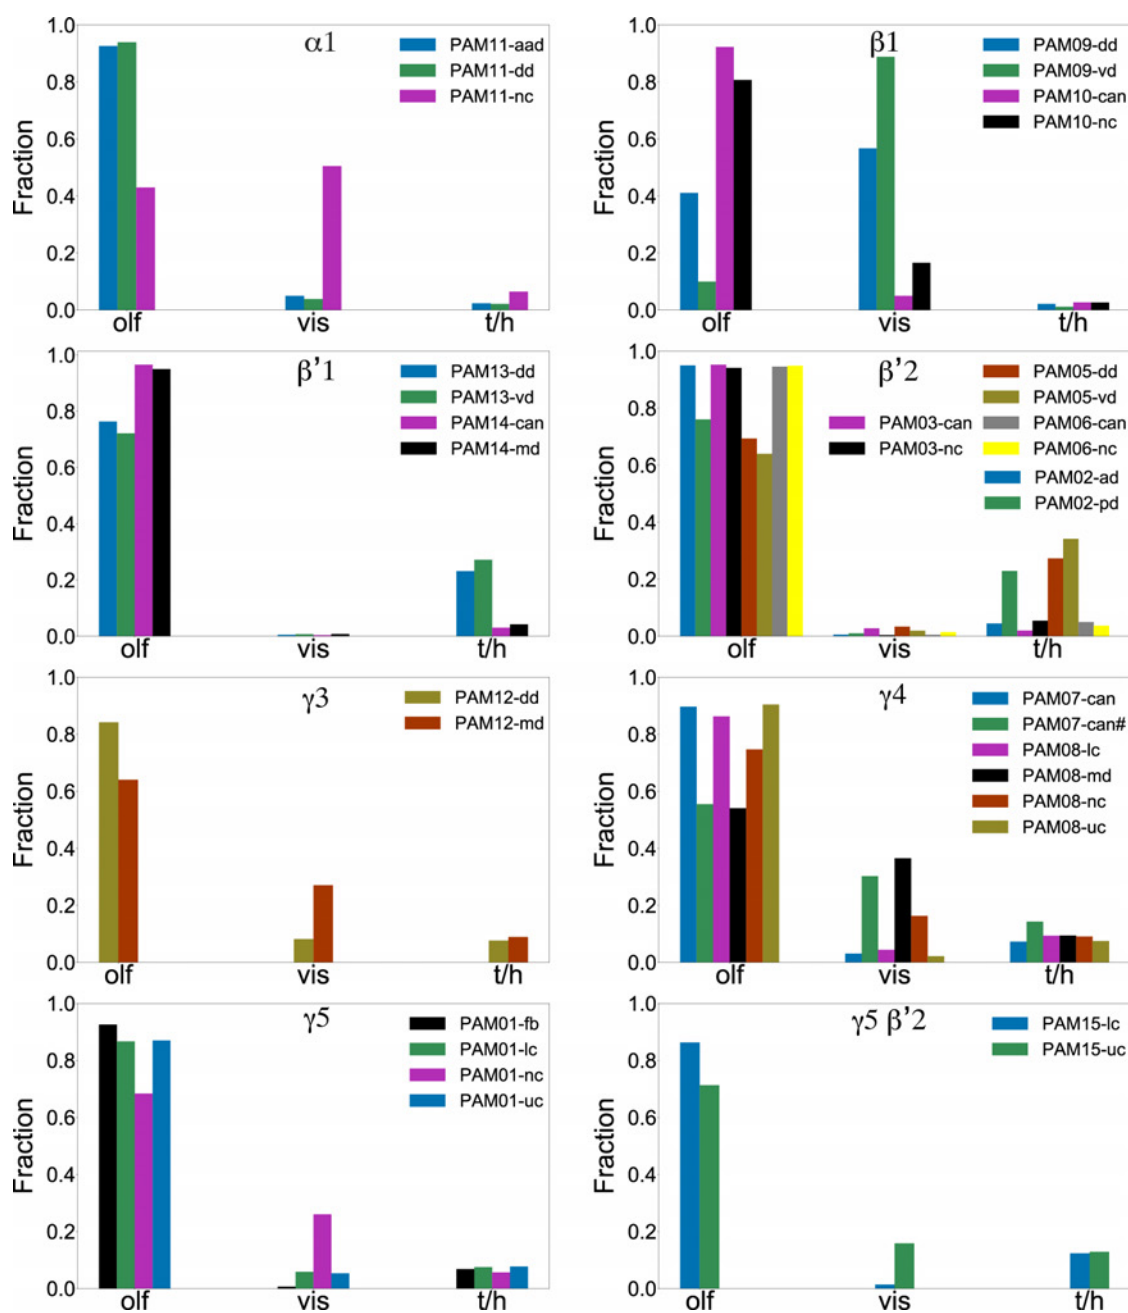

Figure 30-figure supplement 1. DAN subtypes within a compartment can be biased toward KC types representing different sensory modalities.

These plots reveal that in many cases, selective innervation of KC subclasses by particular DAN subtypes within a compartment is organized according to the sensory modality represented by those KCs. Sensory modalities of KCs are assigned according to their PN inputs (derived from the same data as Figure 15-figure supplement 2A). In the indicated compartments, the DANs of a given type are divided into subtypes following criteria from Figure 28. For the PAM07-can ($\gamma4 < \gamma1\gamma2$) subtype, one outlier, indicated by the # sign, which was not apparent with clustering either by morphology or input connectivity, was identified by spectral clustering of DAN-KC connectivity (Figure 29). The y-axis values indicate the fraction of each of the indicated DAN cluster's output it provides to KCs representing three different sensory modalities. The contributions of each KC to this value are weighted by the number of input synapses they receive from DANs of the given type. Olf - olfactory, vis - visual, and t/h - thermo/hyrosensory.

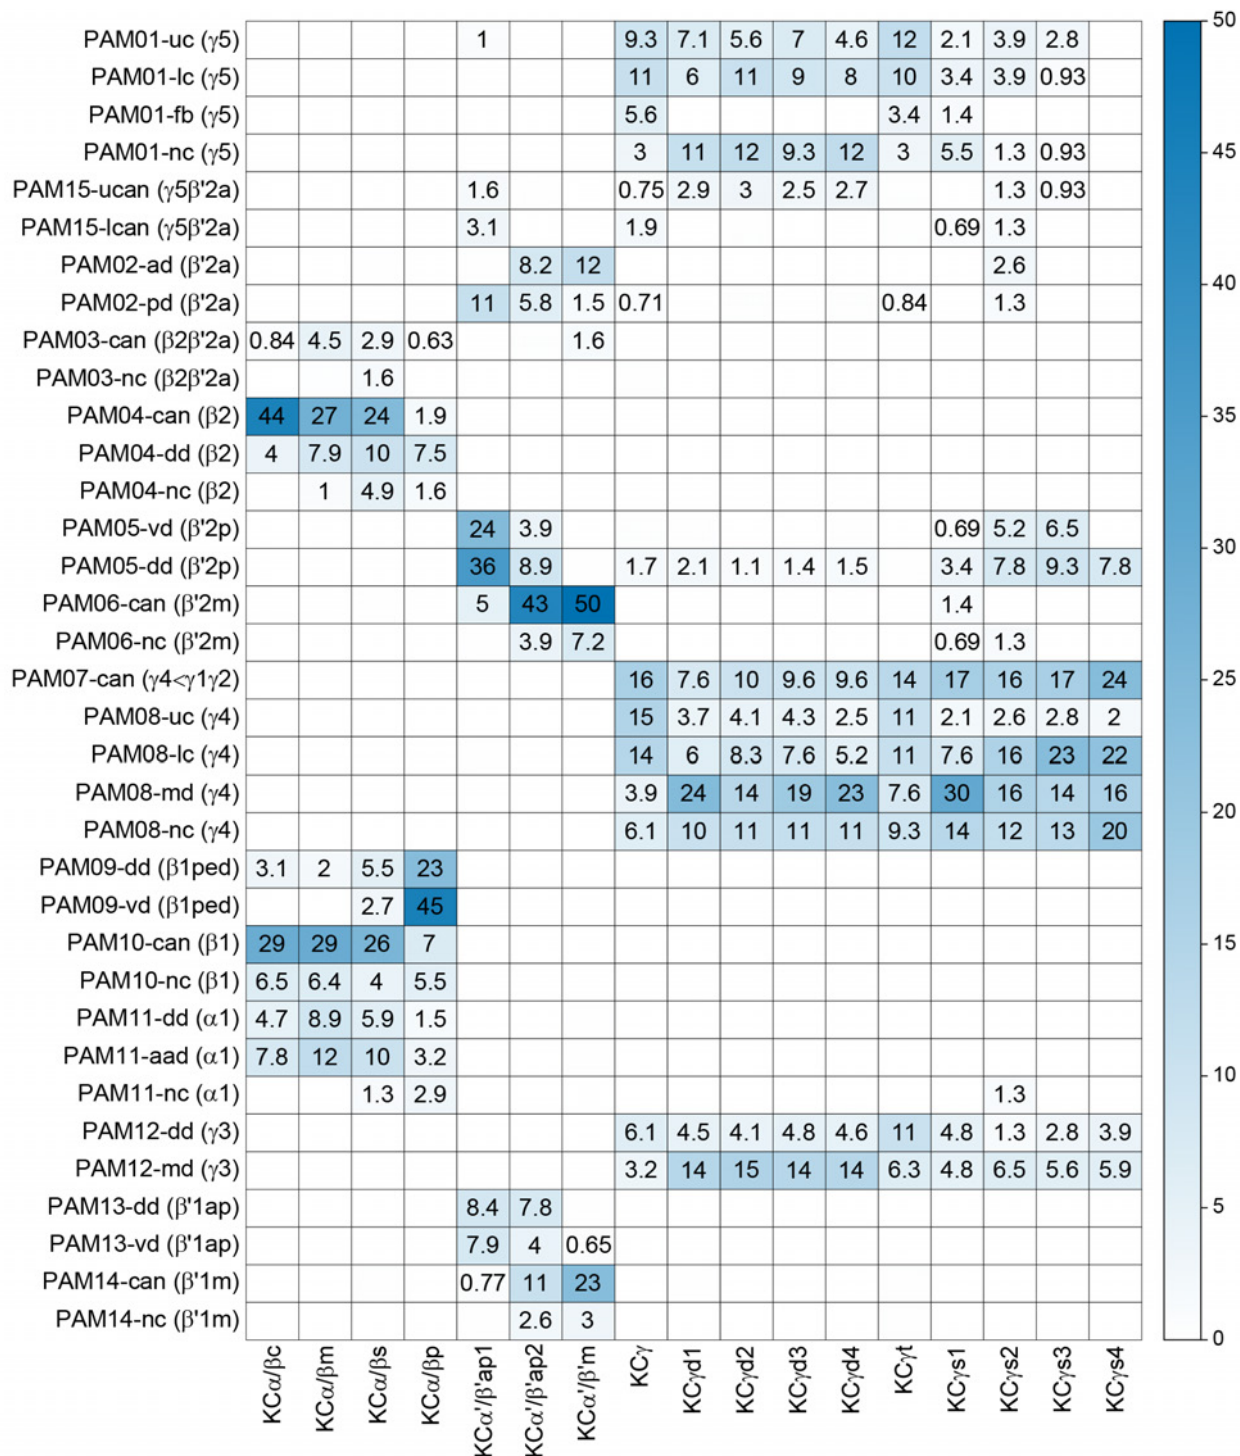

Figure 30-figure supplement 2. PAM DAN subtypes synapse onto specific KC classes within a compartment.

DAN to KC connectivity matrix underlying Figure 30. DAN subtypes, defined by morphological and upstream connectivity clustering (from Figure 28), synapse onto specific types of KCs within a compartment. Each cell of the matrix shows the percentage of inputs provided by a particular DAN subtype, normalized by all DAN inputs to that KC type. DAN subtypes that have axons confined to portions of the same compartment often differ in their KC connectivity. Only connections constituting greater than 0.5% of the KC's total DAN input in the compartment are shown.

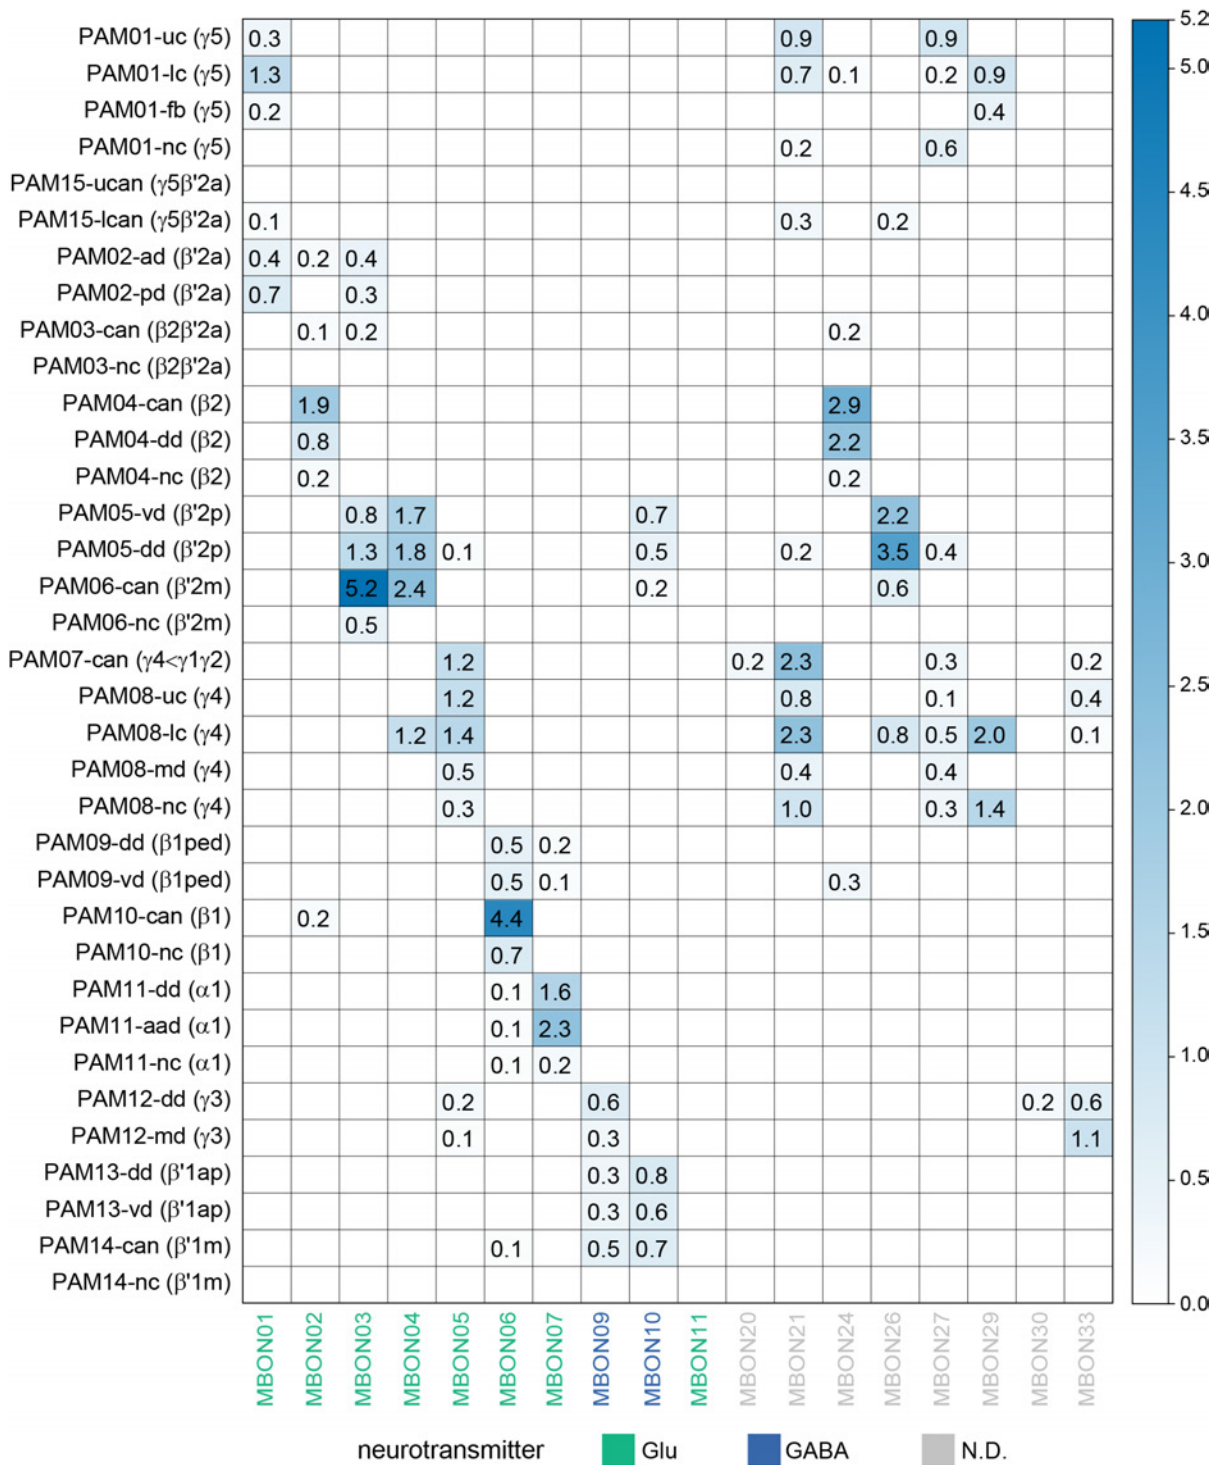

Figure 30-figure supplement 3. PAM DAN subtypes synapse selectively onto particular MBONs within a compartment. DAN to MBON connectivity matrix underlying Figure 30. DAN subtypes as defined by morphological and upstream connectivity clustering (from Figure 28) connect to specific MBONs within the respective compartment. Each cell of the matrix shows the percentage of input provided by the indicated DAN subtype, normalized by the MBON's synaptic input. DAN subtypes that have axons confined to a specific portion of the same compartment often differ in their connectivity to MBONs. Only connections constituting greater than 0.1% of the synaptic input to each MBON are shown.

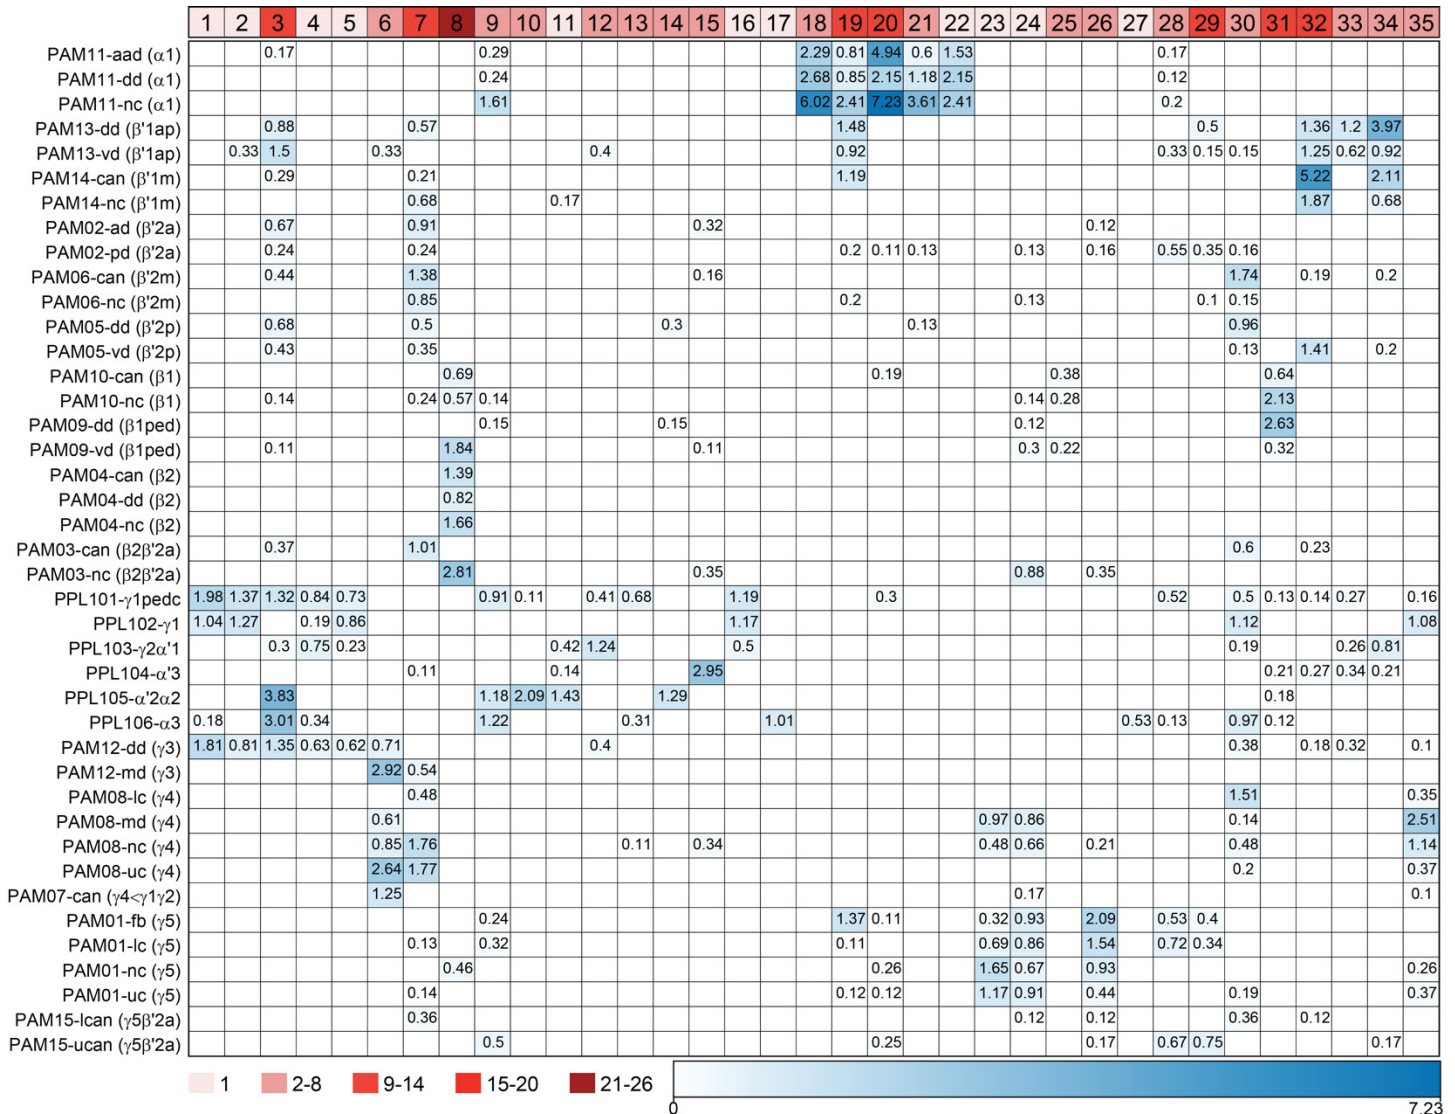

Figure 31. Shared input neurons reveal expected and unexpected across-compartment groupings of DAN subtypes. Matrix representing the connectivity to DAN subtypes provided by the top 50 strongest input neurons to each DAN subtype in the right hemisphere ($n = 913$ neurons, excluding MBONs and MB intrinsic neurons). These inputs are either unique individual neurons (clusters of one) or clusters of multiple neurons grouped according to their morphology. A selection of 35 input clusters are shown, numbered in boxes whose shading reflects the number of neurons that contribute to that cluster (all input clusters are listed in supplemental Table 2). Each cell represents the proportion of the total inputs to the dendrites of the DANs of the respective subtype (y -axis) provided by the input neuron cluster (x -axis). Selected input clusters and innervation patterns are further explored in Figures 32-37. Some DAN subtypes receive inputs from neurons projecting from heavily studied neuropils like the SEZ, the FB, and the LH; for example, clusters 10, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 31 (Figures 33-35). Many clusters selectively connect to groups of DAN subtypes of the PAM or PPL1 type specifically; for example, clusters 7, 8, 11, 12, 13, 14, 15, 29, 32 (Figure 36) and clusters 22, 23, 24, 26, 27 (Figure 35). Some input neuron clusters connect DAN subtypes with opposite/mixed valence; for example, clusters 3, 9, 30, 33, 35 (Figure 37) and cluster 28 (Figure 35; also see Otto et al. 2020). Input neuron clusters can also stand out by the DAN subtypes that they avoid; for example, clusters 3 and 30 (Figure 37). The matrix was thresholded to show inputs over 0.1% of total input to DAN dendrites and the threshold for strong connectivity was defined as 0.5%. The neuropil of the SEZ is not included in the hemibrain database. Therefore, more complete anatomy of DAN input neurons from this region were retrieved from FAFB (Zheng et al. 2018; see Figure 35).

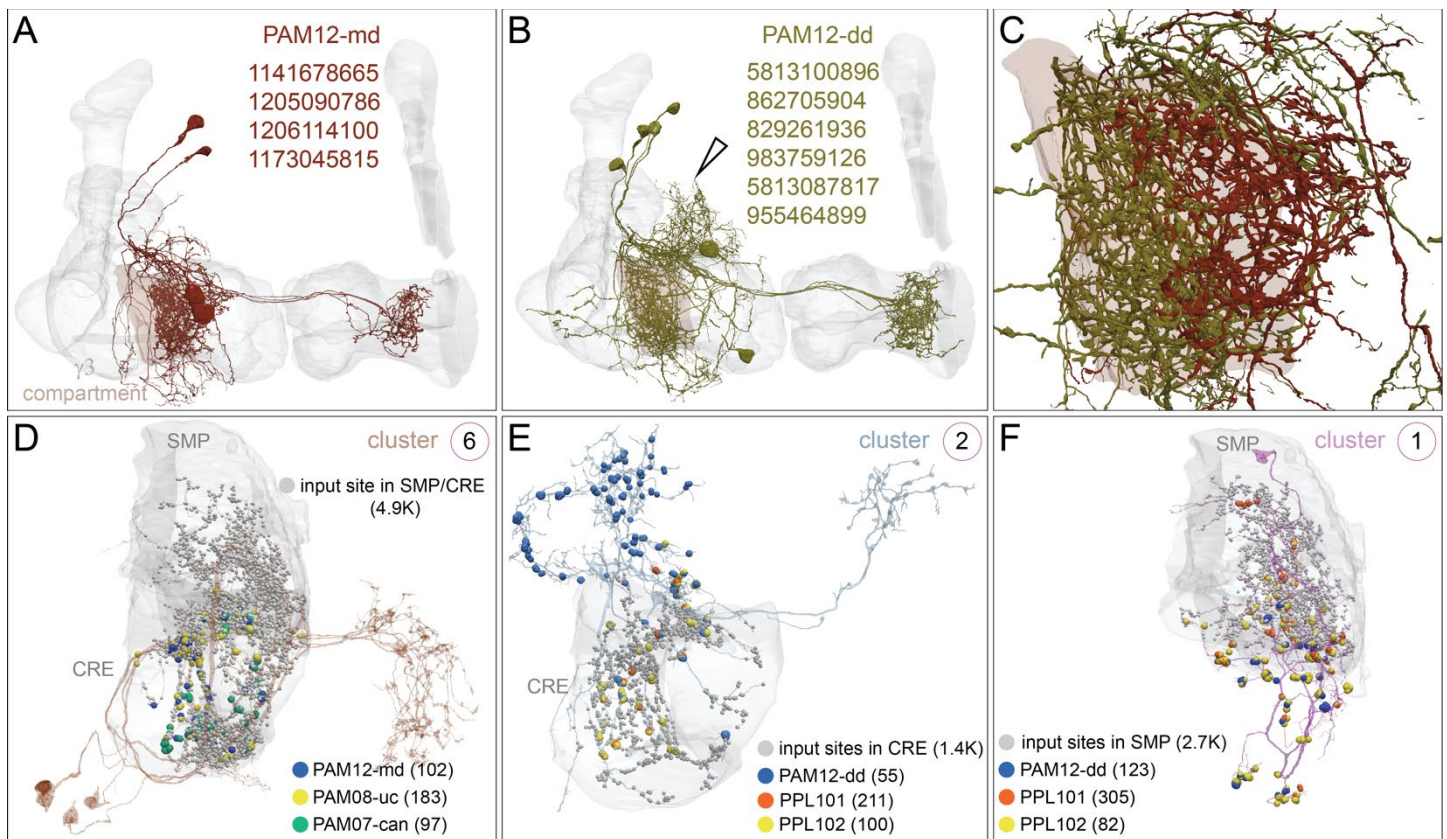

Figure 32. Morphologically distinct subtypes of PAM12-DANs share inputs with either PPL1 or PAM DANs.

(A) The four PAM12-md DANs (maroon) innervate the γ_3 compartment (brown) of the MB neuropil (grey). (B) The PAM12-dd subtype (green) has additional dorsal dendritic branches (open arrowhead) not found in PAM12-md. A seventh PAM12-dd that lacked its ipsilateral axon was excluded from the analysis. (C) The axonal fields of PAM12-md and PAM12-dd DAN subtypes tile the γ_3 compartment (brown), suggesting they modulate different downstream neuronal connections (see Figure 30 for further analyses). (D-F) Strong inputs (see Figure 31) to PAM12-md also specifically synapse onto positive valence PAM DANs, whereas PAM12-dd shares inputs with negative valence PPL1 DANs; synapse numbers are given in parentheses. Circled number in the upper right of each panel refers to the input cluster number in Figure 31. (D) [Cluster 6](#) collectively provides the strongest dendritic input to PAM12-md DANs (blue dots) and is also the strongest input to two DAN subtypes innervating γ_4 , PAM08-uc DANs, (yellow dots) and canonical (can) PAM07-can (green dots). In addition, cluster 6 connects to other PAM08-DANs, but excludes the lower commissure (lc) subtype. (E) A single, morphologically distinct neuron ([cluster 2](#)) connects to the positive valence PAM12-dd (blue dots) and the negative valence PPL101 (γ_1 pedc) (orange dots) and PPL102 (γ_1 ; yellow dots). (F) This single ([cluster 1](#)) neuron provides the strongest dendritic input to positive valence PAM12-dd (blue dots) and the negative valence PPL101 (γ_1 pedc; orange dots) and also synapses onto PPL102 (γ_1 ; yellow dots) DANs. Connections contributing less than 1% of a neuron's total dendritic input have been excluded.

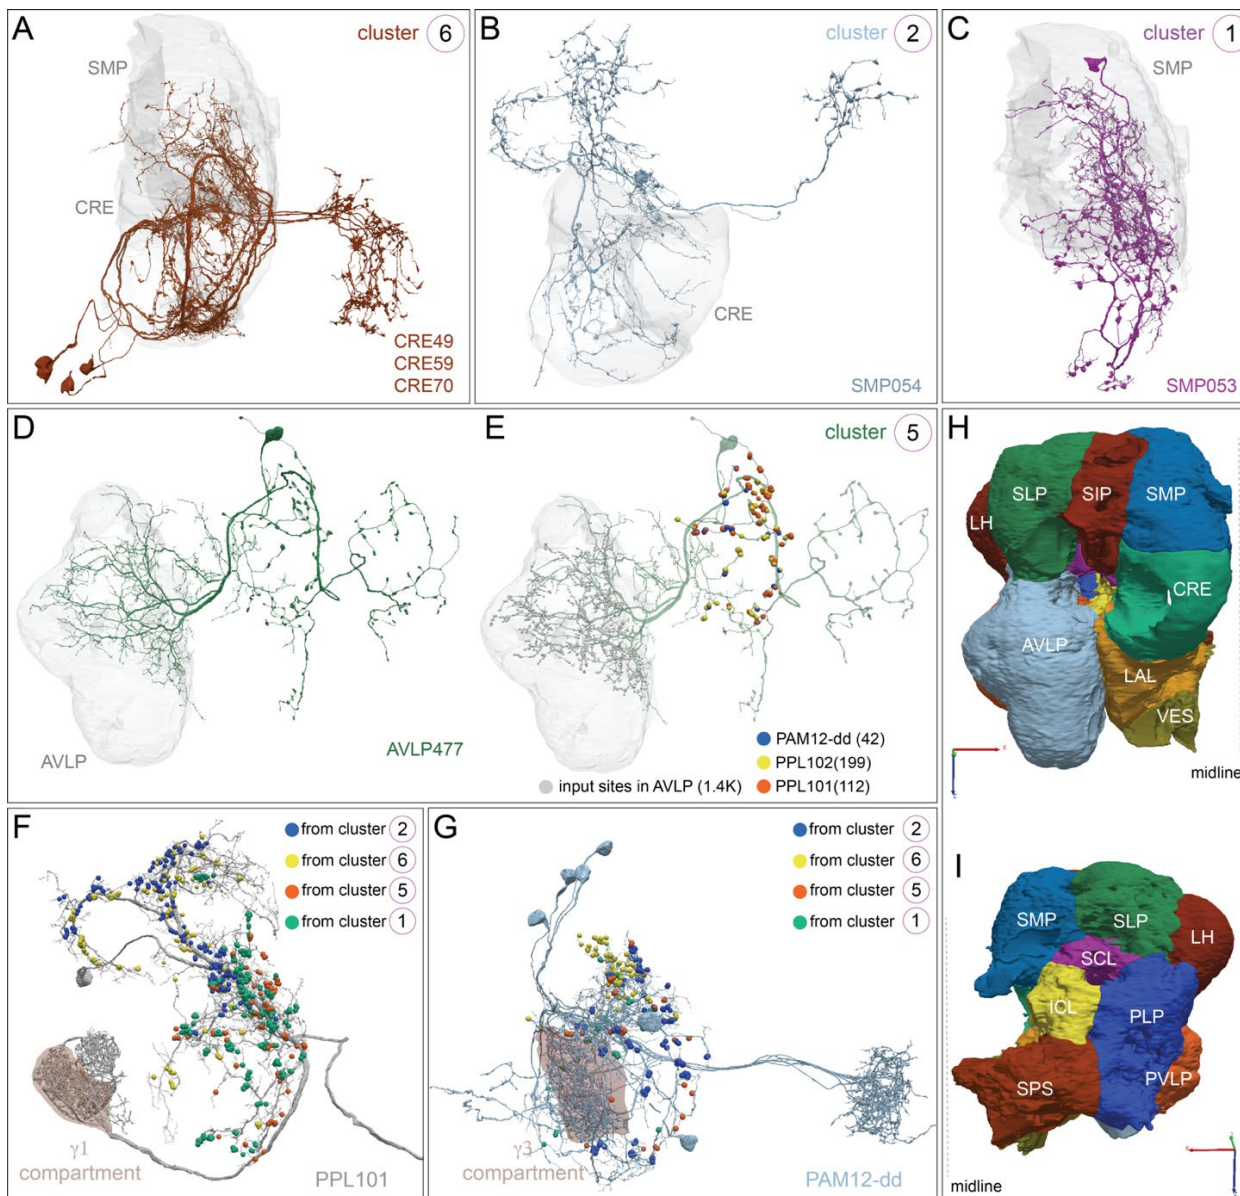

Figure 32-figure supplement 1. Strong inputs to PAM12-dd and PPL101 localize to different dendritic arbors.

More detailed representations of connectivity between input clusters 6, 2, 1 and 5 (Figure 31) and PPL101 and PAM12-dd DANs. Neuropils in which DAN input neurons receive most of their inputs are shown in grey. (A-C) Neurons in cluster 6 (cell types [CRE49](#), [CRE59](#), [CRE70](#)), cluster 2 (cell type [SMP054](#)) and cluster 1 (cell type [SMP053](#)), shown in Figure 32 D-E are shown here without their output synapses marked to allow better visibility of their morphologies. (D and E) Cluster 5 (cell type [AVLP477](#)) shown without synapses (D) and with synapses marked (E) also synapses onto PAM12-dd (blue dots), PPL101 (γ 1pedc; orange dots) and PPL102 (γ 1; yellow dots) DANs; synapse numbers are given in parentheses. (F) Detail of inputs to PPL101, whose outputs are in the γ 1 compartment (brown) and the core of the pedunculus. Inputs from valence-specific clusters 2, 6, 5 and 1 (synaptic input color-coded as indicated) localize to specific branches of PPL101. (G) Detail of inputs to PAM12-dd, whose outputs are in the γ 3 compartment (brown) and which receives input from clusters 2, 6, 5 and 1 (synapses color-coded as indicated). While clusters 5 and 2 inputs are evenly distributed, cluster 6 and 1 localize to the dorsal portion of the PAM12-dd's dendrites. (H and I) Two views of the input neuropils discussed in Figures 32-36; see Figure 2-figure supplement 1 for a key to abbreviations. Connections contributing less than 0.5% of a neuron's total dendritic input have been excluded.

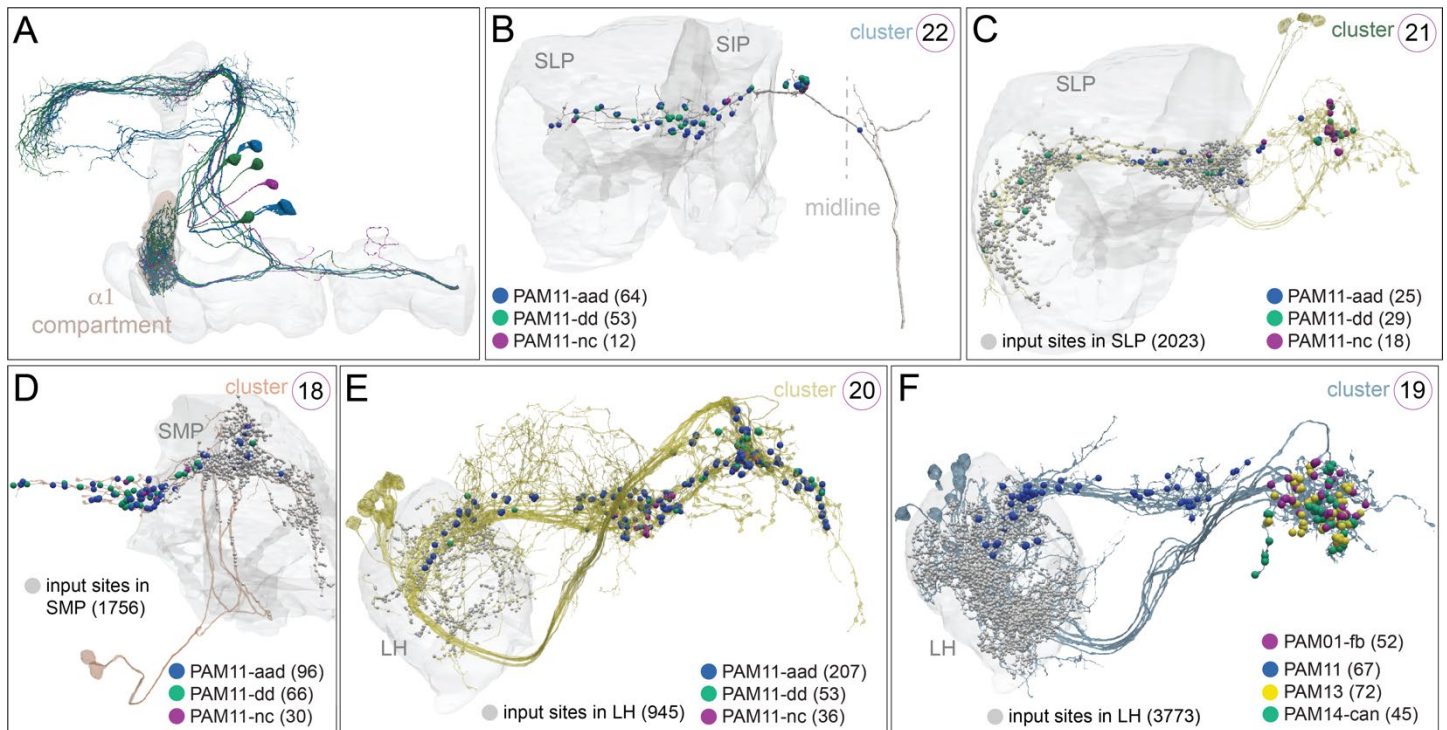

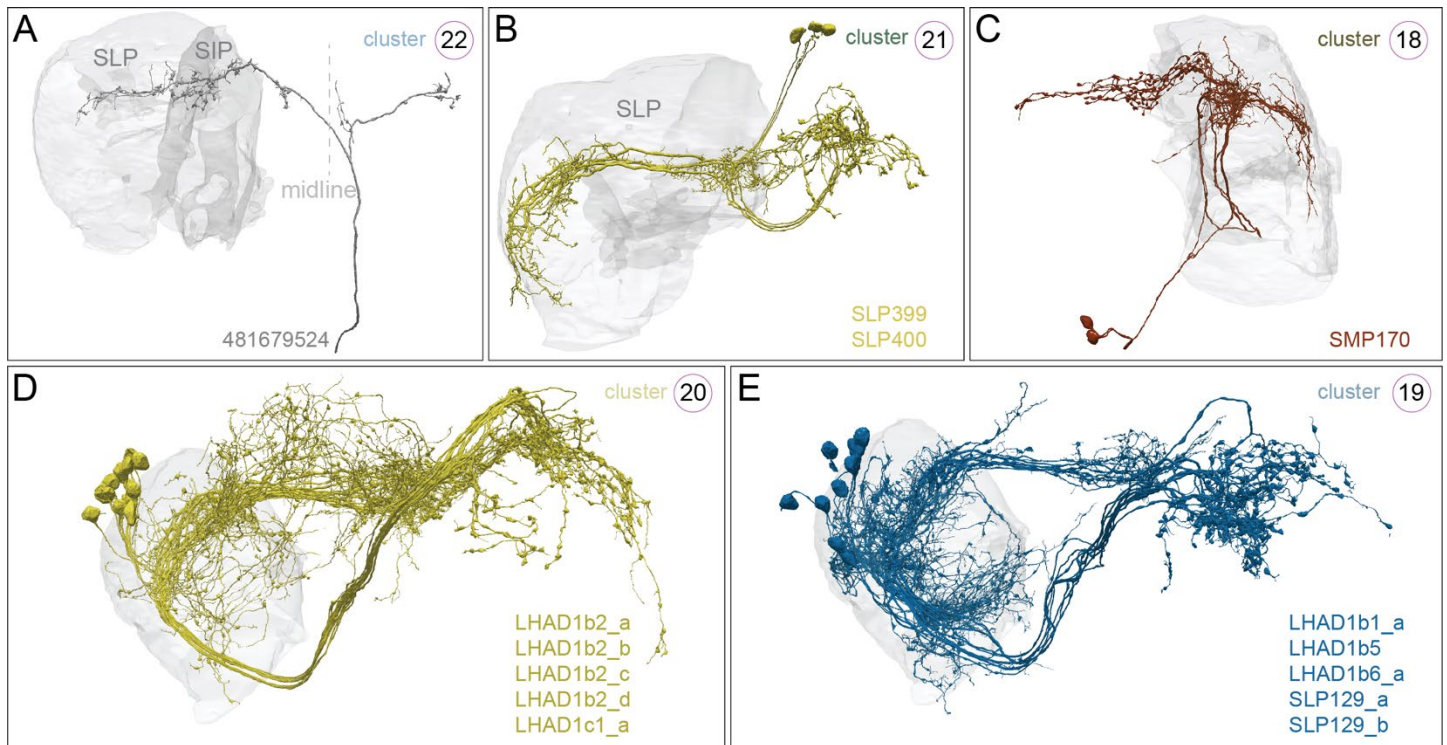

Figure 33. Examples of local neurons, SEZONS, and LHONs that target PAM11 DANs.

(A) All PAM11 DAN subtypes are shown, color-coded as in Figure 28 and 28-figure supplement 1; the MB lobes are shown in grey and the $\alpha 1$ compartment is shaded brown. (B-F) Examples of neurons from clusters in Figure 30 that provide strong input to PAM11 DANs or to PAM11 and other positive valence PAM DANs are shown; cluster identity is indicated by the circled number in the upper right of each panel. Neuropils where DAN input clusters receive their inputs are shown in grey (except for SEZONS whose dendrites are not in the hemibrain volume) and position of output synapses to PAM11 subtypes are shown color-coded; synapse numbers are given in parentheses. Figure 33-figure supplement 1 shows more information about the neurons constituting these clusters. (B) The single neuron in [cluster 22](#), a SEZON, makes synapses to all three subtypes of PAM11 DANs; PAM11 DANs are the only DAN targets of cluster 22. The same applies to its contralateral partner (see figure 35-figure supplement 1A). (C) The local interneurons that make up [cluster 21](#) receive inputs in the SLP and connect to all three PAM11 subtypes, but not to other DANs. (D) The local interneurons that make up [cluster 18](#) (299626157, 361700223) receive inputs in the SMP and connect to PAM11 DANs, but not to other DANs. (E) The LHON [cluster 20](#) connects to all three PAM11 subtypes and weakly to PAM01 and other positive valence PAM DANs (compare to Frechter et al. 2018, Dolan et al. 2019, and Otto et al. 2020). (F) The LHONs [cluster 19](#) connect to all three PAM11 subtypes and also to PAM13 ($\beta'1ap$), PAM14 ($\beta'1m$) and PAM01-fb ($\gamma 5$) DANs. The connections to the PAM11 and the other PAM DANs are located on different primary branches of the cluster 19 neurons. Connections contributing less than 0.5% of a neuron's total dendritic input have been excluded.

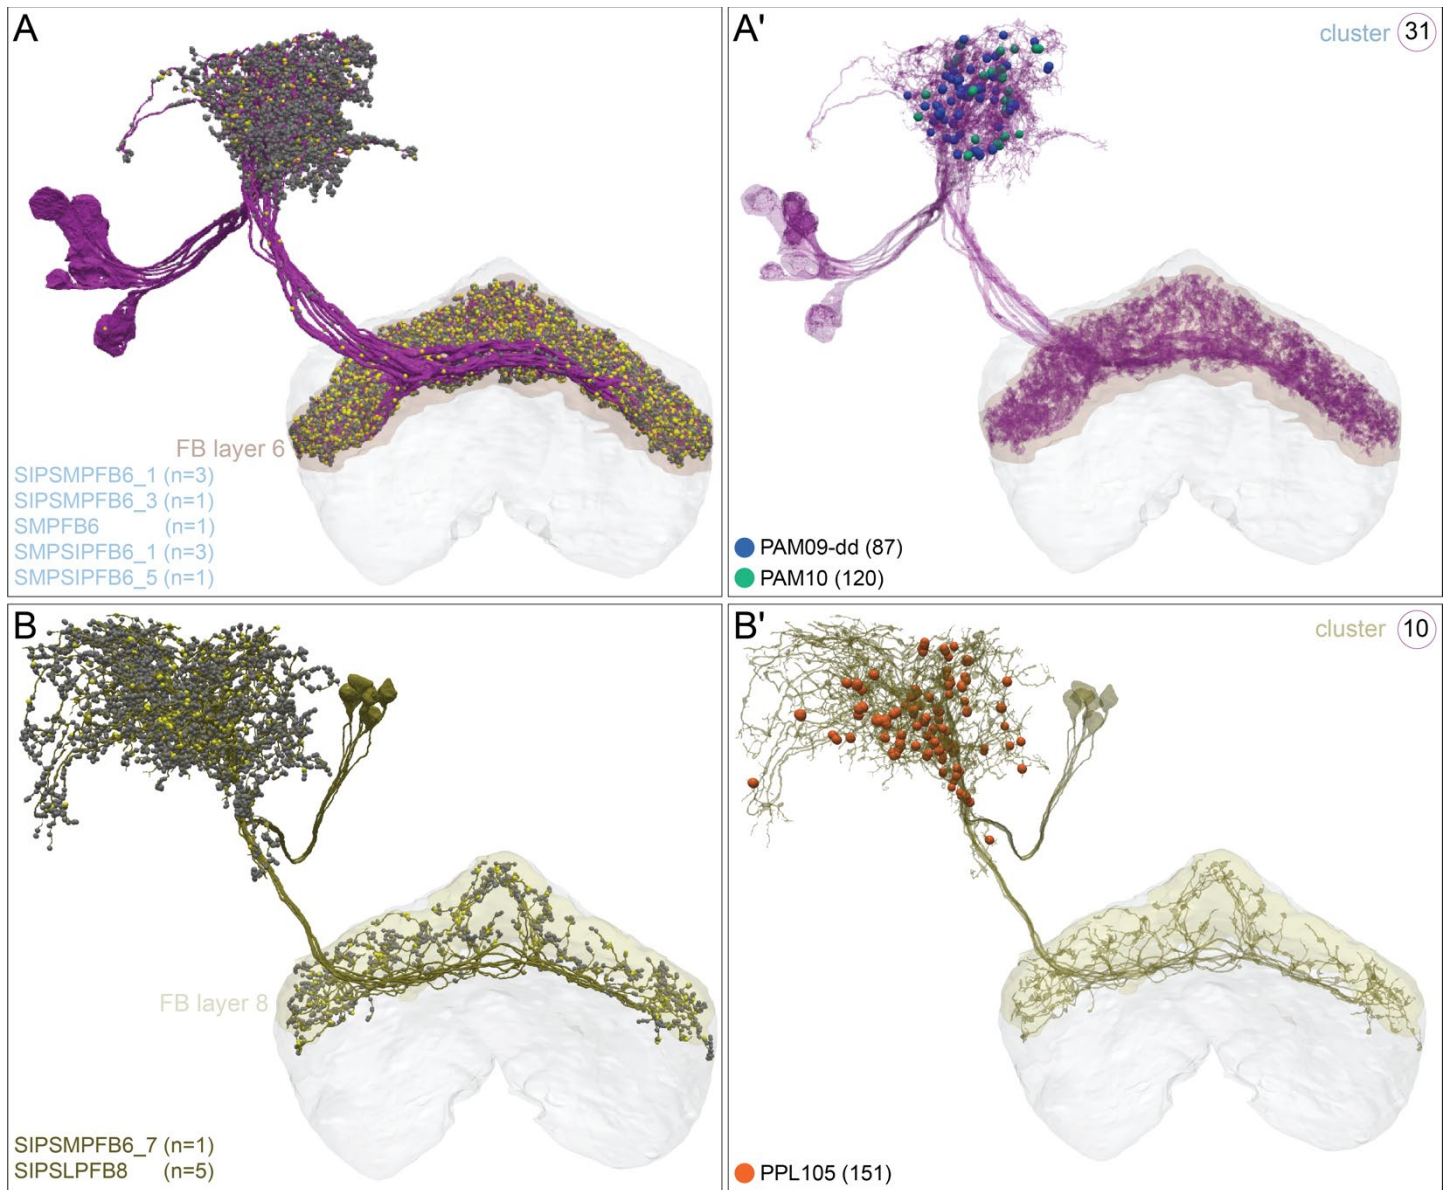

Figure 34. Distinct FB neurons provide input to β lobe PAM or PPL105 DANs.

Two morphological clusters (31 and 10, Figure 31) of neurons from FB are among the strongest DAN inputs. These FB neurons have arbors of mixed polarity both in the SMP and in the FB, as can be seen in panels A and B where their presynaptic and postsynaptic sites are shown in yellow and grey, respectively. (A and A') [Cluster 31](#) neurons are shown in magenta and consists of nine FB layer 6 neurons of five cell types. These neurons synapse onto the dendrites of three potentially positive valence PAM DAN subtypes: PAM09-dd ($\beta 1pedc$; blue dots), and two $\beta 1$ DAN subtypes, PAM10-can and PAM10-nc(dd) (combined in figure; green dots); synapse numbers are given in parentheses. Remarkably, seven of the nine neurons of cluster 31 are connected, via an interneuron, to MBON19 ($\alpha 2p3p$; see Figure 20-figure supplement 1C and Video 29). (B and B') [Cluster 10](#) neurons are shown in yellow and consist of five layer 8 (cell type: SIPSLPFB8) and one layer 6 FB neurons and make synapses in the SMP onto PPL105 ($\alpha'2\alpha 2$; red dots; synapse number is given in parentheses); the negative valence PPL105 is the only DAN they innervate. Connections contributing less than 0.5% of a neuron's total dendritic input have been excluded.

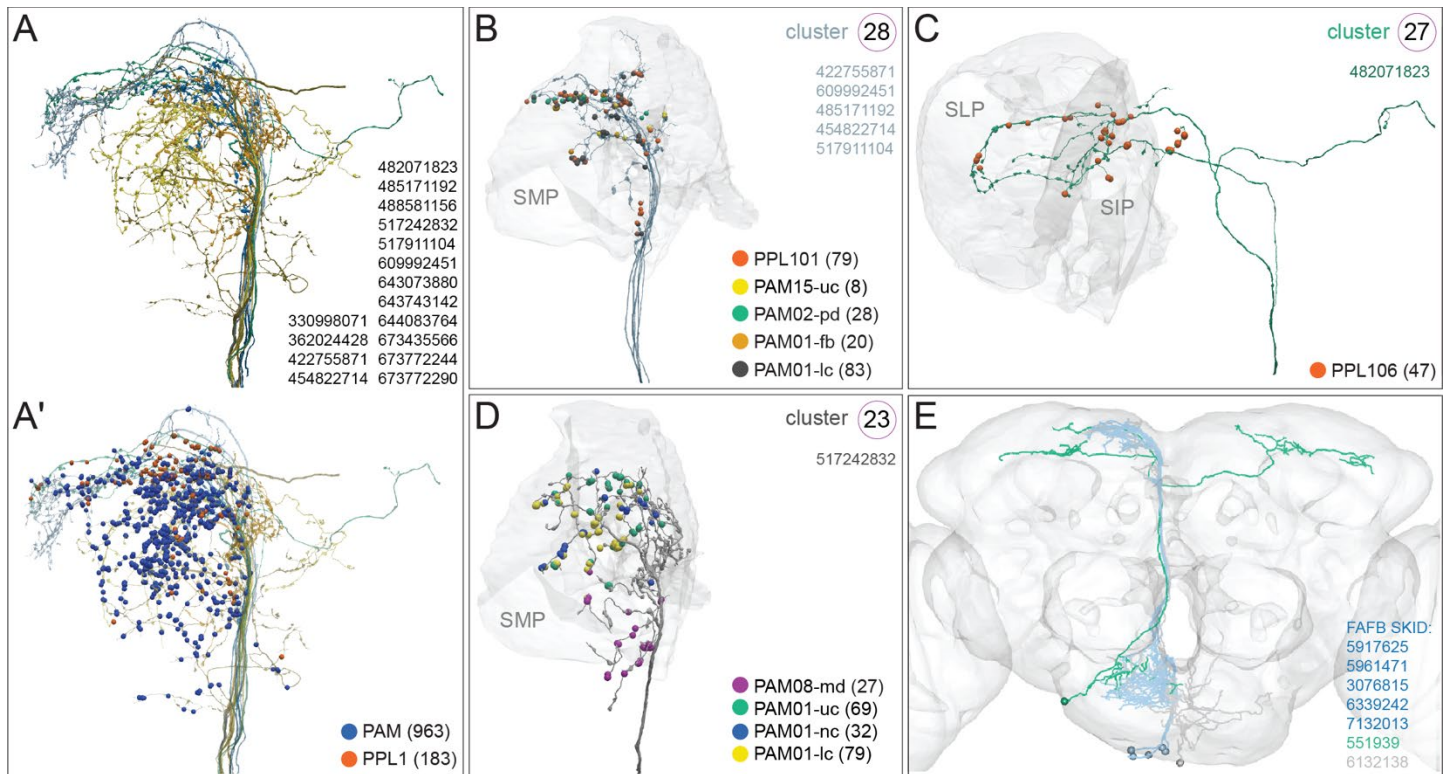

Figure 35. Output neurons from different areas of the SEZ tile the SMP where they synapse onto select DAN subtypes. (A) Axons from multiple SEZON cell types in clusters 22, 23, 24, 26, 27, and 28 (see Figure 31) that provide strong inputs to DAN subtypes are shown together. (A') The same SEZON axons shown with synapses connecting to PAM DANs (blue, from 5 clusters) and to PPL1 DANs (red, from 2 clusters); synapse numbers are given in parentheses. (B) The five neurons of SEZON [cluster 28](#) (light blue; these neurons correspond to the SEZON01 cluster 5.4.1 of Otto et al., 2020) branch in the SMP and synapse onto the PPL101 (red), PAM01-lc (black), PAM01-fb (orange), PAM02-pd (green), and PAM15-uc (yellow) subtypes; synapse numbers are given in parentheses. (C) The single neuron in SEZON [cluster 27](#) (green) branches in the SMP and SIP and synapses only onto PPL106; synapse number is given in parentheses. (D) The single neuron in SEZON [cluster 23](#) (grey) branches in the SMP and connects to positive valence DANs: PAM01-lc (yellow), PAM01-uc (green), PAM01-nc (blue), and PAM08-md (magenta); synapse numbers are given in parentheses. (E) The axons of SEZON neurons can be matched to those in the FAFB EM volume (Zheng et al., 2018) to permit the retrieval of their dendritic field, which resides in tissue that is missing from the hemibrain dataset; skeleton ID numbers from FAFB are shown. FAFB matches to hemibrain SEZONs are shown and colored to match their hemibrain counterparts (colors correspond to (B-D)). Their dendritic fields differ, suggesting these SEZON clusters are likely to convey distinct information. Connections contributing less than 0.5% of a neuron's total dendritic input have been excluded.

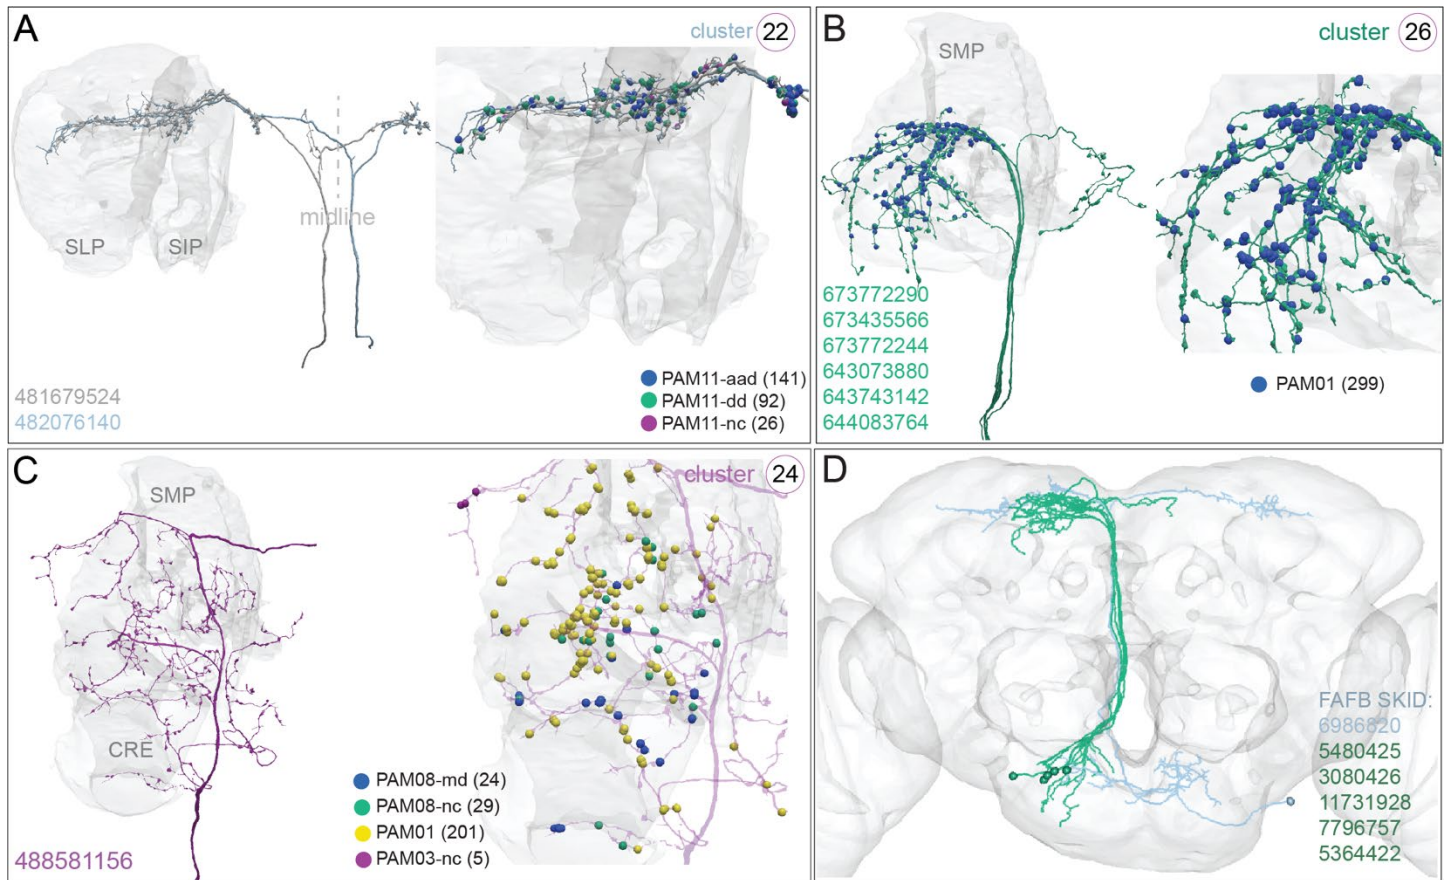

Figure 35-figure supplement 1. Most strongly connected SEZON clusters exclusively synapse onto positive valence PAM DANs.

(A-C) Further examples of clusters consisting of SEZONs that connect to specific DAN subtypes. In each panel the neuronal morphology is shown on the left with the brain regions where they contact DANs shown in grey, and on the right a higher magnification view of their output synapses onto specific DAN types are shown, color coded, with synapse numbers given in parentheses. The threshold for connectivity is 0.5% of the DANs total inputs (Figure 31). (A) The neurons of SEZON [cluster 22](#) (481679524) and its contralateral partner (482076140) branch in the SMP and SLP and synapse onto all 3 PAM11 subtypes (compare to Figure 33). (B) The six neurons in SEZON [cluster 26](#) branch in the SMP and connect to positive valence $\gamma 5$ DAN subtypes (blue) and weakly to PAM15 ($\gamma 5\beta'2a$) and PAM02 ($\beta'2a$) subtypes. (C) The single neuron in SEZON [cluster 24](#) branches in the SMP and connects specifically to PAM08-md ($\gamma 4$; blue) and PAM08-nc subtypes (green), all PAM01 ($\gamma 5$) subtypes (yellow), as well as the PAM03-nc ($\beta 2\beta'2a$) subtype (magenta). (D) The axons of SEZONs in (A and B) can be matched to those in the FAFB EM volume (Zheng et al. 2018). This registration permits the retrieval of their dendritic fields, which reside in tissue that is missing from the hemibrain dataset. FAFB matches to hemibrain SEZONs are shown and are colored to match their hemibrain counterparts in panels (A) and (B). The dendritic fields differ, suggesting these SEZONs convey distinct information. Connections contributing less than 0.5% of a neuron's total dendritic input have been excluded.

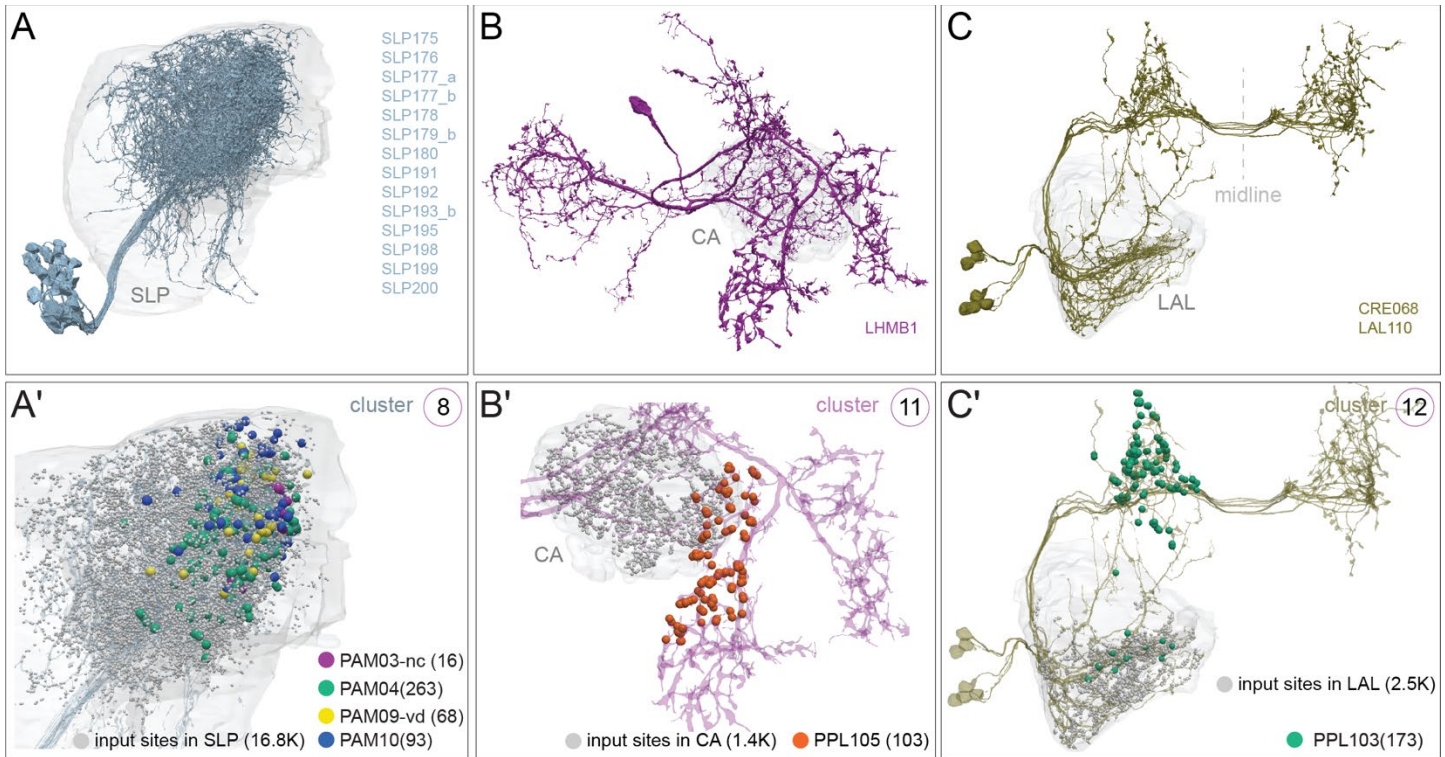

Figure 36. A number of input neurons specifically target DAN groups of the PAM or PPL1 clusters.

Neurons providing strong input to PAM or PPL1 DANs are shown. Neuropil areas of inputs to these neurons are shown in grey in (A-C) and synapses to DANs are shown color-coded in (A'-C'); synapse numbers are given in parentheses. The threshold for connectivity is 0.5% of the DANs total inputs (Figure 31). (A, A') [Cluster 8](#) is comprised of 26 neurons of 14 similar cell types which provide input to subtypes of β -lobe PAM DANs in the SLP: PAM10 (β_1 ; blue); PAM09-vd (β_1 pedc; yellow); all PAM04 subtypes (β_2 ; green); and the PAM03-nc ($\beta_2\beta'2a$; magenta) subtype. (B, B') The single neuron in [cluster 11](#) receives inputs in the CA and connects to PPL105 ($\alpha'2\alpha_2$; red). (C, C') The seven neurons in [cluster 12](#) ([LAL110](#), [CRE068](#)) receive inputs in the (LAL) and provide the strongest input to PPL103 ($\gamma_2\alpha'1$; green). Connections contributing less than 0.5% of a neuron's total dendritic input have been excluded.

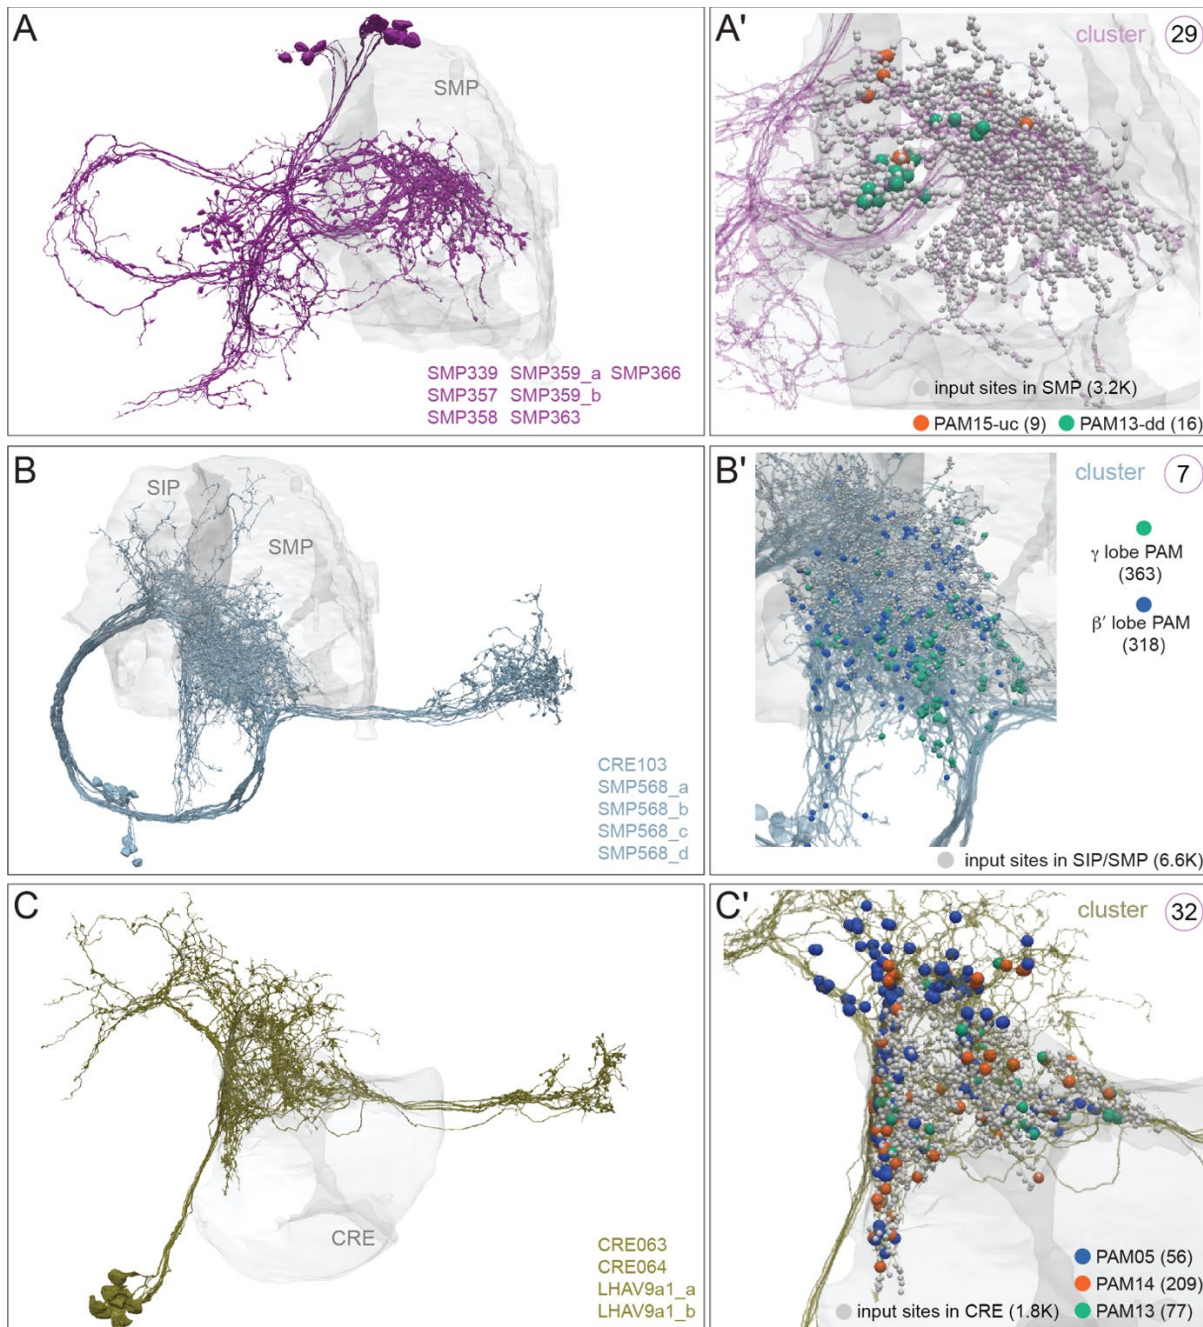

Figure 36-figure supplement 1. Inputs specific to PAM DANs.

Neurons providing strong input to DANs of the PAM cluster are shown. Neuropil areas indicated (grey) and synapses to DANs are color coded; synapse numbers are given in parentheses. (A, A') The nine neurons of [cluster 29](#) fall into seven cell types and receive inputs in the SMP and connect to PAM15-uc ($\gamma 5\beta'2a$; red) and the PAM13-dd ($\beta'1ap$; green). (B, B') The 13 neurons of [cluster 7](#) fall into five cell types and receive inputs in the SMP and SIP and connect strongly to PAM DANs that are restricted to the β' (blue synapses) and the γ lobes (green synapses): PAM13 ($\beta'1ap$), PAM06 ($\beta'1m$), PAM02 ($\beta'2a$), PAM06 ($\beta'2m$), PAM05 ($\beta'2p$), PAM03 ($\beta 2\beta'2a$) and PAM12-md ($\gamma 3$), PAM08 ($\gamma 4$), PAM01 ($\gamma 5$), PAM($\gamma 5\beta'2a$). (C, C') [Cluster 32](#) has nine neurons of four cell types that receive some inputs in the CRE. Cluster 32 provides strong input to PAM14 ($\beta'1$) subtypes (red synapses) and is also upstream of the PAM05-vd ($\beta'2p$) subtype (blue synapses) and all PAM13 ($\beta'1ap$) subtypes (green synapse). The threshold for connectivity is 0.5% of the DANs total inputs (Figure 31).

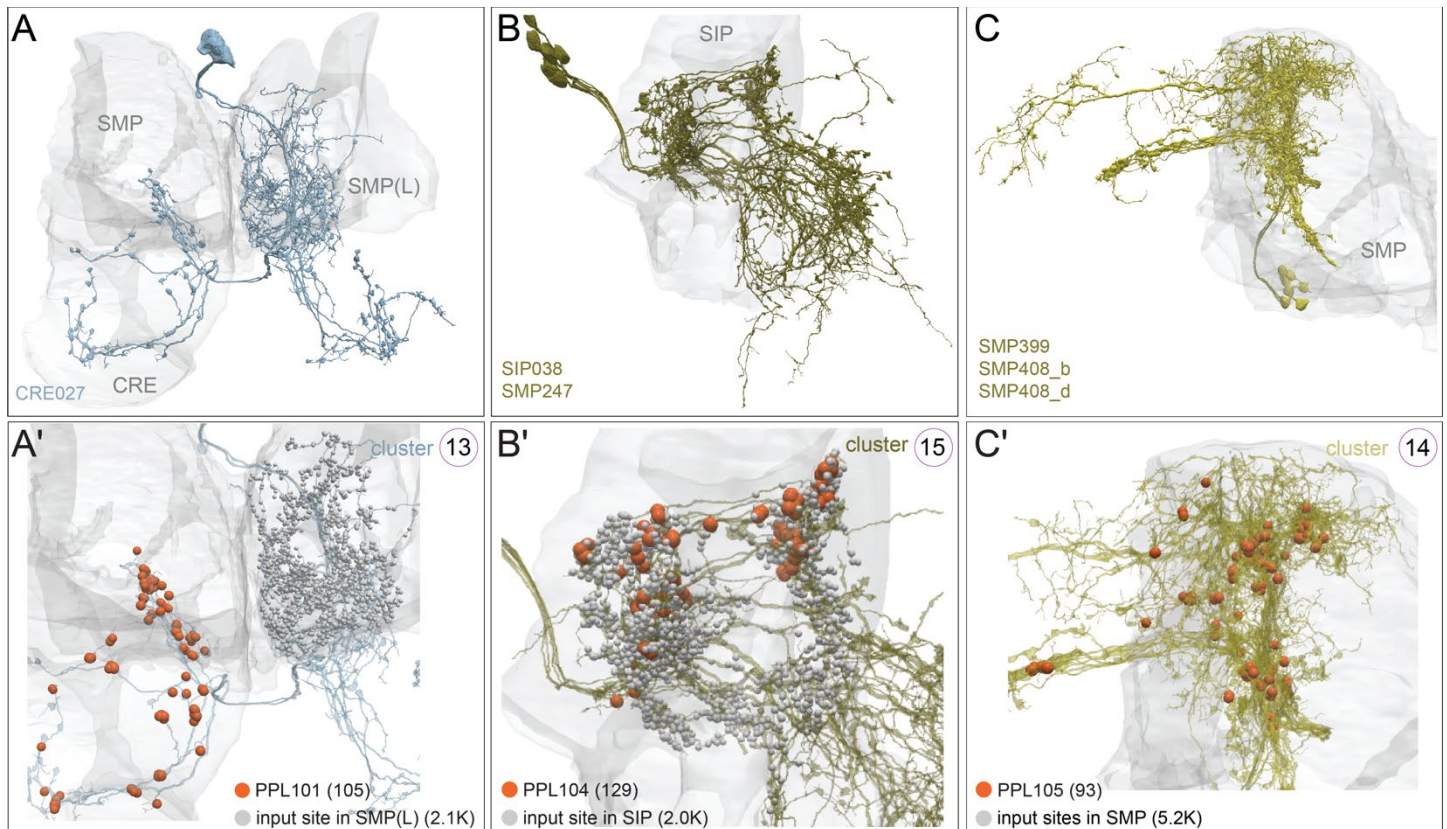

Figure 36-figure supplement 2. Inputs specific to PPL1 DANs.

Neuropil areas indicated (grey) and synapses to DANs are color coded; synapse numbers are given in parentheses. (A, A') The two neurons (light blue) of [cluster 13](#) receive inputs in the contralateral SMPs and connect to the negative valence PPL101(γ 1pedc; red) DANs. (B, B') [Cluster 15](#) has six neurons receiving inputs in the SIP and provide strong input to PPL104 (α '3). (C, C') The seven neurons of [cluster 14](#) receive inputs in the SMP and are strongly connected to the PPL105 (α '2 α 2). The threshold for connectivity is 0.5% of the DAN's total inputs (Figure 31).

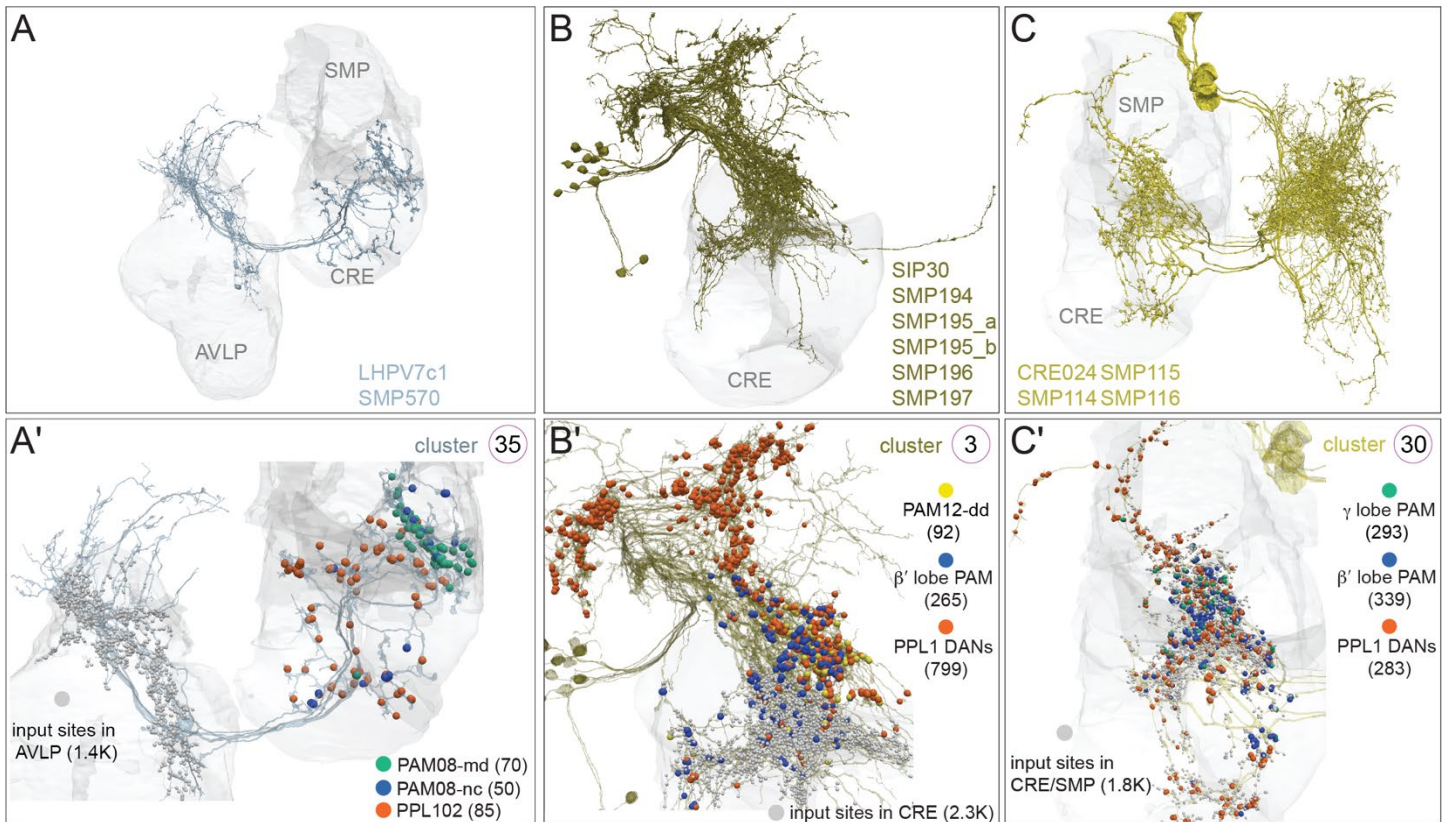

Figure 37. Neurons that provide strong input to both PAM and PPL1 DANs.

Neuropil areas indicated in grey and synapses to DANs are color coded; synapse numbers are given in parentheses. (A, A') The four neurons of [cluster 35](#) receive inputs in the AVLP and provide strong input to the PAM08-md (γ 4; green) and PAM08-nc (blue synapses) subtypes as well as the PPL102 (γ 1) DAN (red synapses). (B, B') The 13 neurons of [cluster 3](#) receive some inputs in the CRE; they constitute the strongest input to PPL105 (α '2 α 2) and PPL106 (α 3) and also connect to PPL101 (γ 1pedc), PPL102 (γ 1), and PPL103 (γ 2 α '1) (all PPL1 DAN synapses combined, red), all of the β ' lobe PAM DAN subtypes (blue synapses) and the PAM12-dd (γ 3) subtype (yellow synapses). (C, C') [Cluster 30](#) has four neurons that receive inputs in the SMP and CRE and are upstream of negative valence PPL1 neurons (PPL101, PPL102, PPL105, and PPL106; red synapses) and PAM DANs innervating the β ' (blue synapses) and γ (green synapses) lobe (PAM08, PAM01, PAM03, PAM05, PAM06). While both cluster 3 and 30 connect to both PPL1 and PAM DANs, cluster 30 connects to γ lobe PAM DANs, in contrast to cluster 3 favoring β ' lobe PAM DANs.

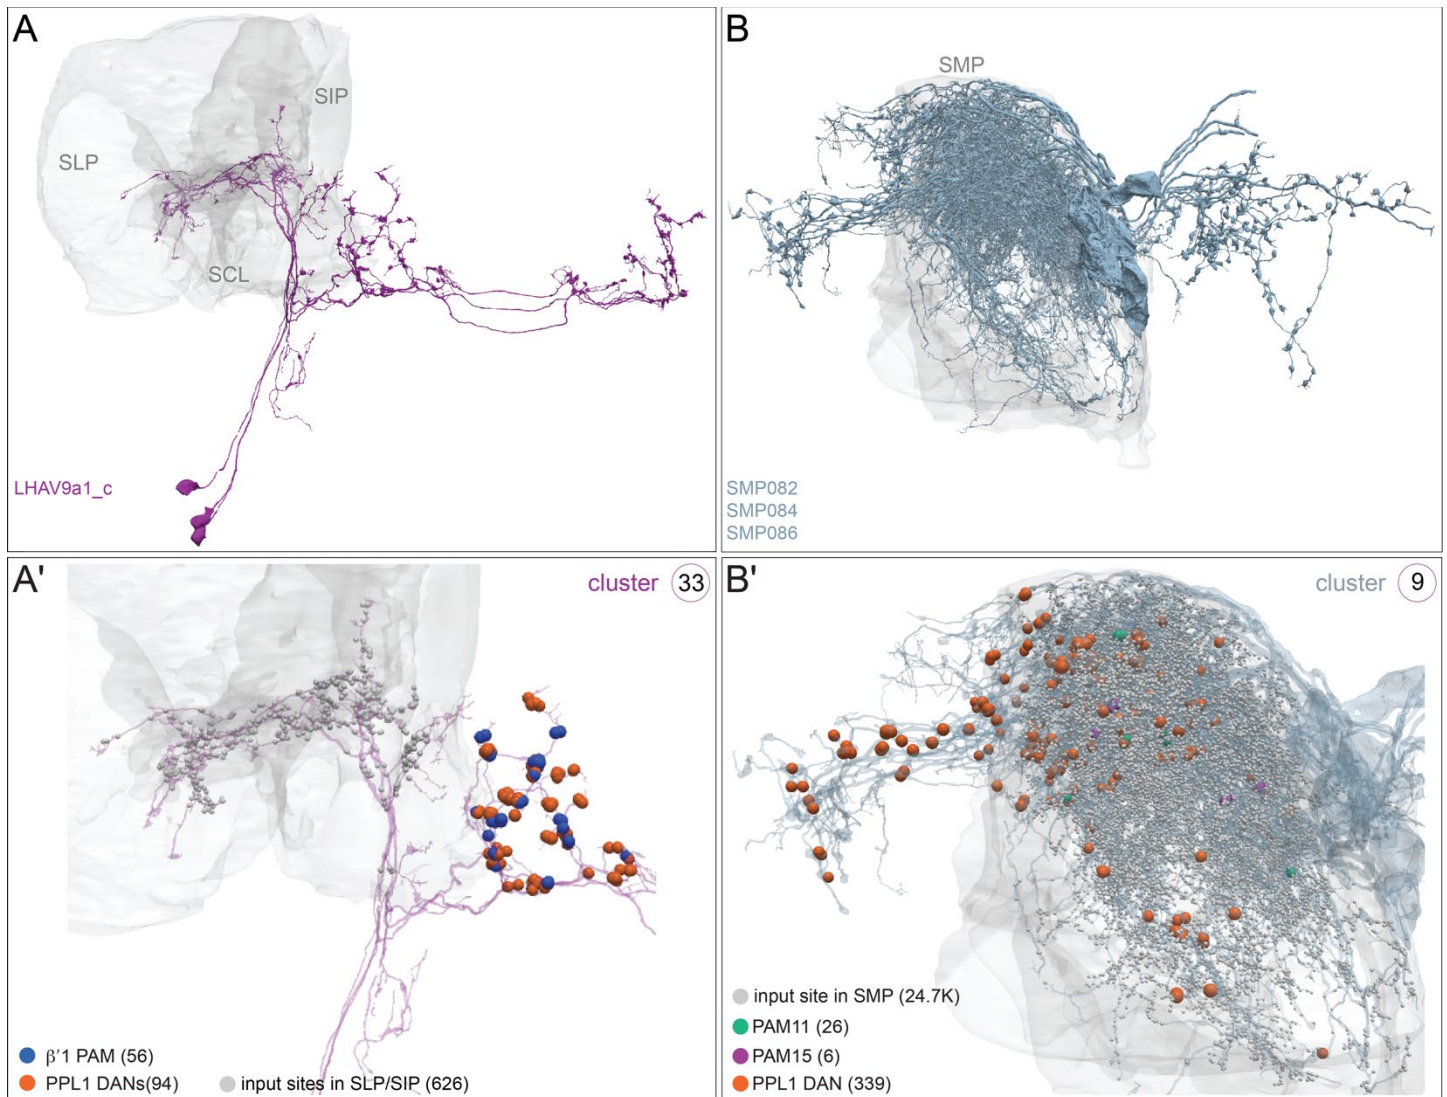

Figure 37-figure supplement 1. Additional examples of neurons providing common input to both PAM and PPL1 DANs. Neuropil areas where neurons of cluster 33 and cluster 9 receive input are shown in grey and their synapses onto DANs are color coded; synapse numbers are given in parentheses. (A, A') The three neurons of [cluster 33](#) receive inputs in the SIP, SLP, and SCL and connect to both PAM13 (β' 1ap) subtypes (blue synapses) and to a collection of PPL1 DANs (PPL101, PPL102, PPL103 and PPL104; red synapses). (B, B') [Cluster 9](#) has six neurons that receive inputs in the SMP and connect to the negative valence PPL1 DANs (PPL101, PPL102, PPL105 and PPL106; red synapses). Cluster 9 is also upstream, but more weakly, of positive valence PAM DANs (dark blue synapses) including all PAM11 subtypes (green synapses), the PAM15 subtypes (magenta synapses) and more weakly to PAM01-lc and PAM01-fb subtypes.

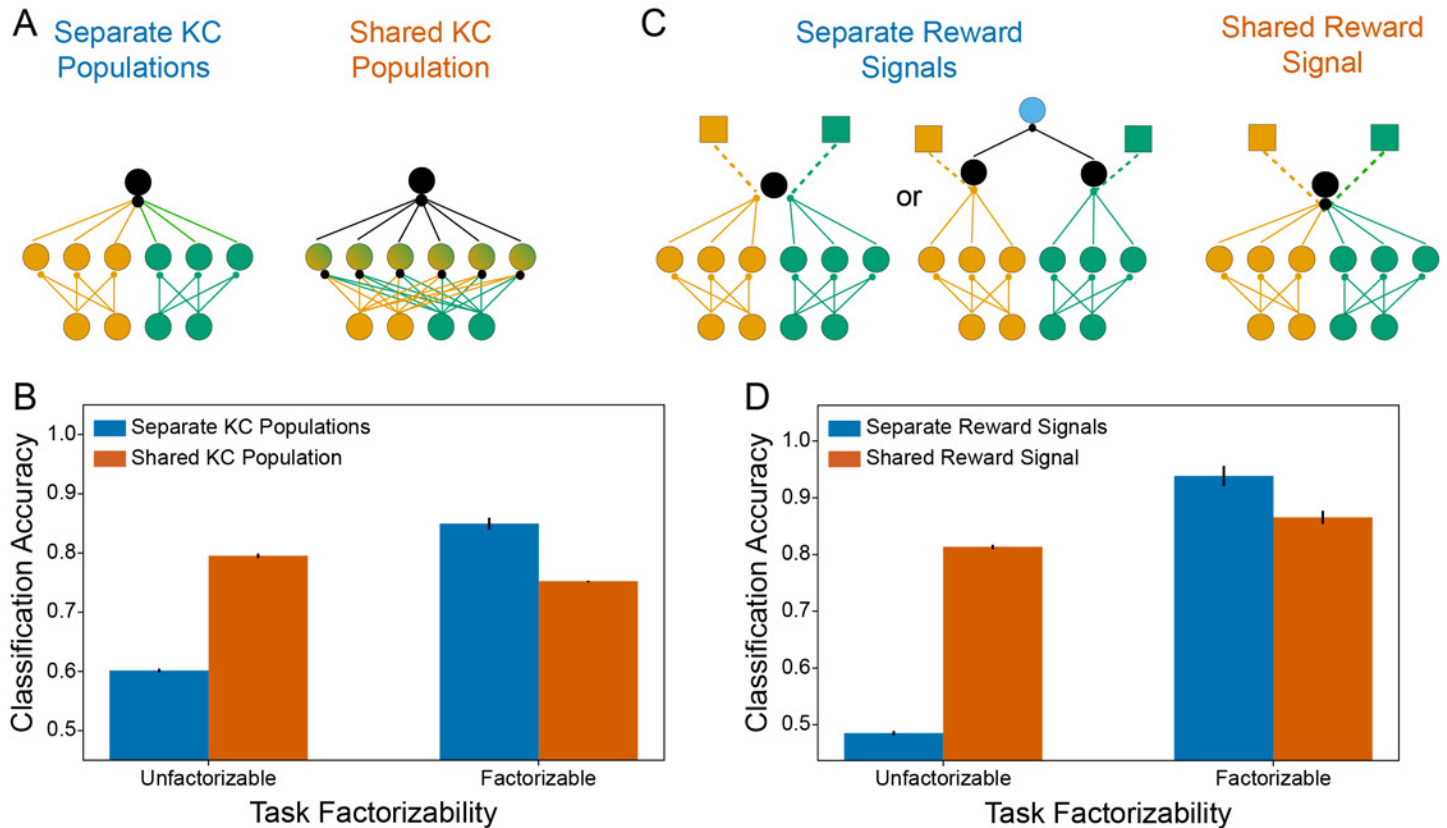

Figure 38. Effects of segregated or mixed-modality signals.

(A) Schematic of two possible architectures for an MB-like circuit, in which KCs are either specialized for one sensory modality (left) or receive mixed input (right). Bottom layer circles represent PN inputs, middle layer circles represent KCs, and black output circles represent MBONs. Green and yellow shades indicate different sensory modalities. (B) Task performance in a stimulus discrimination model for the architectures shown in A. Stimuli consist of random binary patterns in two sensory modalities. In the “factorizable” task, the stimulus from each modality has an assigned valence (positive or negative) and the overall valence is positive only if both constituent valences are positive. In the “unfactorizable” task, each stimulus is randomly assigned its own unique valence, irrespective of its constituent modalities. A linear readout, modeling an MBON, is fit to discriminate the valences of the stimuli based on the activations of the KC population. The linear fit procedure corresponds to the experienced-based plasticity of KC-MBON synapses. Task performance is defined as the binary classification accuracy—that is, the frequency with which the thresholded response of the MBON corresponds correctly to the valence of the input—of this MBON readout. 25 stimuli are presented in the unfactorizable task and 200 in the factorizable task, to make overall task difficulty comparable. Error bars represent standard error over 20 simulations. (C) Schematic of possible architectures for DAN-dependent plasticity in an MB-like circuit. In the leftmost model, DANs (colored squares) modulate KC-MBON synapses for KCs of a particular sensory modality. The second-to-left model depicts two MBONs, each integrating input from KCs of a particular sensory modality, and each with its own corresponding DAN, that additively converge onto a common output (blue). These two models are functionally equivalent, and hence are grouped together under “separate reward signals.” In the rightmost model, there is a single MBON, and DANs modulate all the KC-MBON synapses (right). (D) Task performance in a stimulus discrimination model (same as B) for the architectures shown in C. For each task the optimal KC structure from B is used (“separate” for the factorizable task, “shared” for the unfactorizable task).

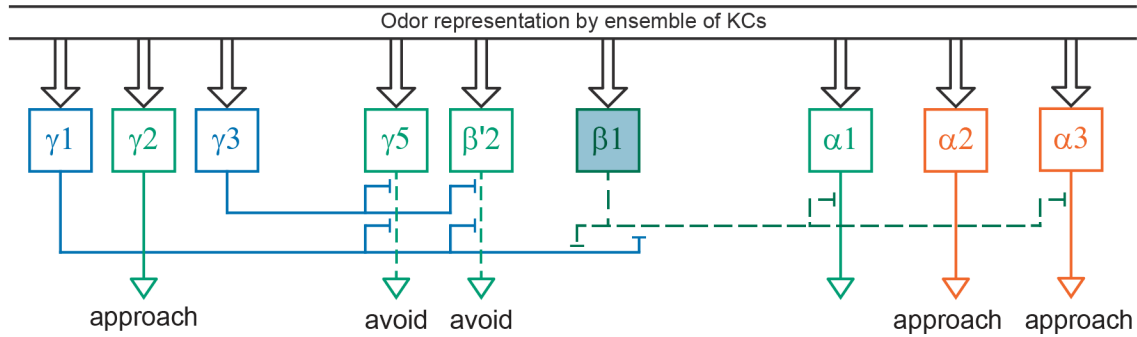

Figure 39. Schematic of subcompartment DAN and MBON innervation within γ_3 .

The two PAM12 (γ_3) DAN subtypes likely represent opposite valence based on their shared input with either aversively reinforcing PPL1-DANs or appetitively reinforcing PAM08 (γ_4) DANs. Whereas PAM12-md DANs selectively innervate the visual γ_d KCs, the PAM12-dd DANs innervate both γ_d and γ_m (olfactory) KCs. The dendrite of atypical MBON30 is restricted to the olfactory γ_m (olfactory) KCs and its DAN input is exclusively from the PAM12-dd subtype. In contrast, the dendrite of atypical MBON33 preferentially collects γ_d KC input and receives input from both PAM12-md and PAM12-dd DANs. The GABAergic MBON09 ($\gamma_3\beta'1$) pools γ_m and γ_d KC input, receives DAN input from PAM12-md and selectively synapses onto MBON30.

Naive

Shock trained

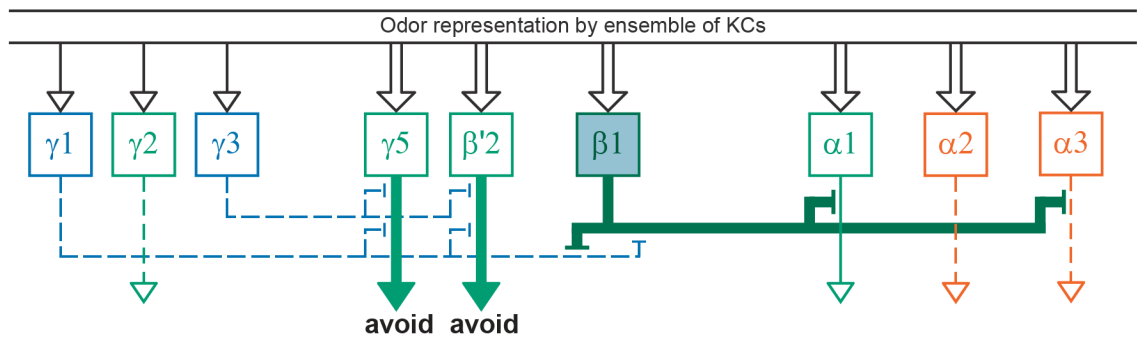

Figure 40. MBON network representation of aversive memory.

Shock responsive DANs innervating γ_1 , γ_2 and γ_3 depress odor-specific KC synapses onto the respective MBONs. Depression of MBON11 ($\gamma_1\text{pedc}>\alpha/\beta$) and MBON09 ($\gamma_3\beta'1$) releases their feedforward inhibition onto the avoidance-directing γ_5 and $\gamma'2$ MBONs. In addition, MBON11 release increases the inhibitory effect of the MBON06 ($\beta_1>\alpha$) onto the approach-directing α_1 and α_3 compartments. Repetitive aversive training trials, and a release from inhibition also allows the DANs in α_2 and α_3 to depress odor-specific KC synapses onto the respective approach directing MBONs. These changes together leave the network in a configuration to direct strong odor-specific avoidance behavior.

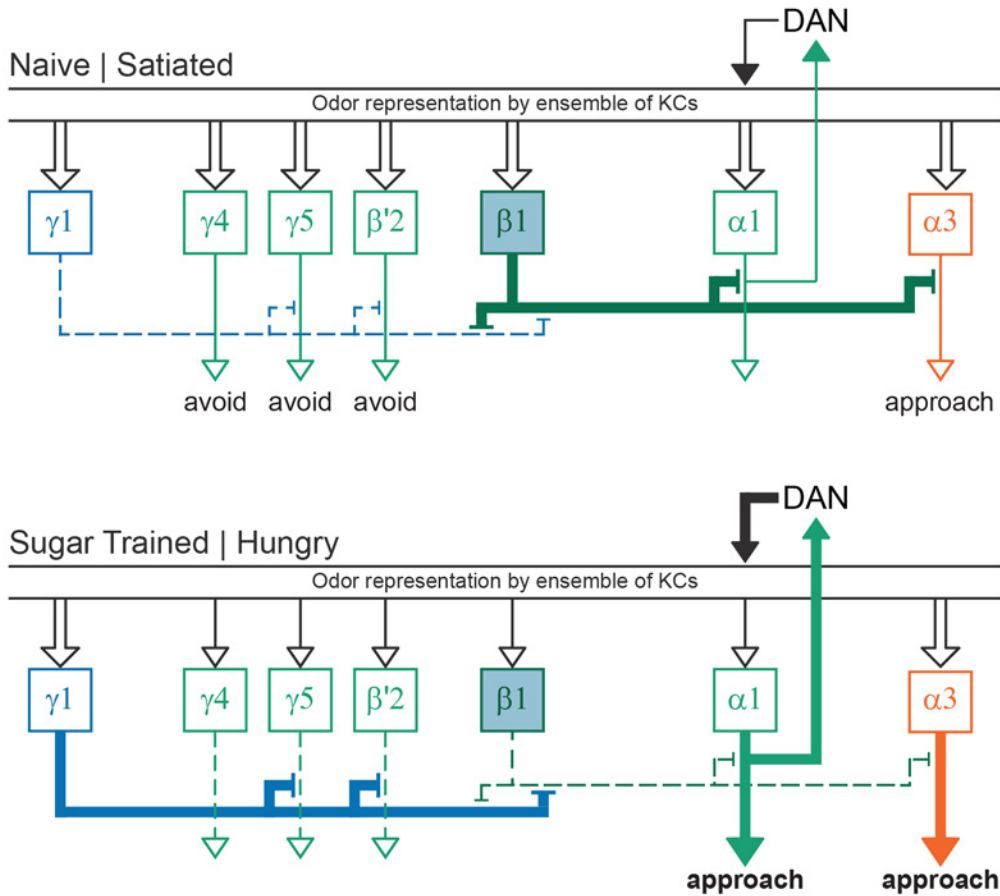

Figure 41. MBON network representation of appetitive memory.

Sugar-responsive DANs innervating $\gamma4$, $\gamma5$, $\beta'2$ and $\beta1$ depress odor-specific KC synapses onto the respective MBONs. Depression of the odor-specific response of MBON06 ($\beta1 > \alpha$) reduces odor-specific feedforward inhibition onto the MBON07 ($\alpha1$) and MBON14 ($\alpha3$). This frees $\alpha3$ to direct odor-driven approach behavior and increases activity in a recurrent $\alpha1$ MBON07-PAM11aad DAN loop to consolidate long-term appetitive memory. MBON11 ($\gamma1pedc > \alpha/\beta$) is sensitive to satiety state and is more responsive when the fly is hungry. Hunger therefore further promotes appetitive memory formation and expression by increasing inhibition onto MBON01 ($\gamma5\beta'2a$) and $\beta'2$ MBONs and by further reducing the feedforward inhibitory effects of MBON06 ($\beta1 > \alpha$) MBON within $\alpha1$ and $\alpha3$. These changes together leave the network in a hunger state-dependent configuration that directs strong odor-specific approach behavior.
