Abstract

24 Automatic analysis of larval zebrafish electrocardiographs (ECG) is essential for high-throughput
25 measurements in environmental toxicity assays, cardiotoxicity measurements and drug screening. We have
26 developed a MATLAB based software is built on methods that have previously been used to analyze
27 human ECG, such as the Pan-Tompkins algorithm and Wavelet. For the first time these sophisticated tools
28 have been applied to larval zebrafish ECG to automatically characterize the heart-beat waveforms. The
29 ability of the automated algorithm to detect the QT interval for both normal and pharmacologically altered
30 larval ECG is found and compared to previously used software that is built into LabChart® (AD
31 Instruments). Using wavelet transforms it is shown that the typical larval ECG features are within the
32 frequency range of 1 to 31 Hz. It is also shown that the automated software is capable of detecting QTc
33 (heartrate corrected heartbeat interval) changes within pharmacologically altered zebrafish larval ECG. The
34 automated process is a significant improvement on the approaches that were previously applied to the
35 zebrafish ECG. The automated process described here that is based on established techniques of analyzing
36 ECG can sensitively measure pharmacologically induced changes in the ECG. The novel, automated
37 software is faster, more sensitive at detecting ECG changes and less dependent on user involvement, thus
38 minimizing user error and human bias. The automated process can also be applied to human ECG.

39

40

41

Introduction

42 Using zebrafish larvae for chemical compound screening is becoming increasingly important for
43 cardiac drug development. It has been previously shown that the zebrafish electrocardiogram (ECG) is
44 similar to mammals. Another advantage of the zebrafish model is that a minimal amount of chemicals are
45 necessary for drug testing and embryo production is fast and inexpensive [1]. Furthermore, using mammals
46 for preliminary screening is expensive, slow and requires enormous numbers of animals. Video-recording

47 of zebrafish embryos' heart activity is currently used for drug screening, but unlike ECG recording it lacks
48 the temporal and dynamic resolution necessary for cardiac cycle component analysis [2-4]. To aid
49 development of high-throughput, high fidelity methods to simultaneously and automatically record ECGs
50 from larval zebrafish, analysis tools that automatically characterize larval ECG signals under control
51 conditions and after drug treatment are desirable.

52 Presented herein is the first successful attempt to develop analysis tools based on algorithms and
53 methods that have previously been used to characterize human ECG, including the Pan-Tompkins
54 algorithm and wavelet transform analysis implemented in MATLAB. These tools are compared to
55 techniques that have previously been used to analyze zebrafish larval ECG based on the software packages
56 offered by AD Instruments (LabChart®).

57

58 **Methods**

59 **Data acquisition**

60 The data used to investigate the analysis tools is larval zebrafish ECG that was taken from 3 days post
61 fertilization larvae using the methods outlined in [5]. The baseline ECG was recorded for approximately 2
62 minutes before verapamil was added and the ECG was recorded for a further 25 minutes. This data
63 represents the typical ECG of a zebrafish larvae recorded in our lab and a typical drug response as
64 previously demonstrated in our previous paper [5].

65 **Data Extraction**

66 After the recording, the data was split into 8, 1-minute sections, labelled chronologically as A, B, C, D, E,
67 F, G, H and exported from LabChart® as a MATLAB compatible data format. Section A was taken from
68 ECG recorded before the drug was introduced to the solution whereas sections B-H were recorded
69 afterwards. Each section was analyzed separately using the different tools outlined above to determine
70 parameters such as the heart rate and the QTc.

71 **Down-sampling the Data for MATLAB Programs**

72 All of the programs written for MATLAB use some initial down-sampling to speed up the processing of the
73 algorithms. Assuming that all the relevant information in the zebrafish ECG occurs well below 100 Hz the
74 program down samples to a sampling rate of $f_s=200$ Hz. In the MATLAB code this appears as:

```
75  
76 %MATLAB ALGORITHM TO DOWNSAMPLE ECG  
77 %% Down-sample to 200 Hz sampling rate  
78 out = ~rem(FS,200)*FS/200 ;
```

79

80

81 **Determining the frequency of the components of the zebrafish ECG**

82 To investigate which filtering bandwidth would best capture the ECG features whilst removing any low-
83 frequency drift and high-frequency interference, the sections were first analyzed using a wavelet transform
84 in MATLAB. To perform the transform, 20 seconds of raw ECG data was taken from section A and
85 transformed using a Gaussian wavelet combined with an in built MATLAB function, as described in above.
86 The result of the wavelet transform was outputted as a contour map and an approximate of the
87 characteristic frequencies of the ECG features were measured visually. Due to space-time localization it is
88 not possible to state categorically that the characteristic frequency of each feature was perfectly aligned to
89 the correct time signature, however the graphical output could be used as a guide of the approximate
90 frequency of each feature. This frequency of each R wave and T wave within the section was recorded and
91 tabulated. Graphical outputs of the ECG wavelet transform. From the tabulated data the mean and standard
92 deviation of the characteristic frequency of the R and T waves were determined. These values were used to
93 tailor the upper frequency cut-off to remove higher frequency noise without attenuating the ECG signal.
94 The upper frequency limit was set to the mean R-wave characteristic frequency plus two standard

95 deviations. Assuming that the R-wave frequency is normally distributed about the mean, this would suggest
96 that approximately 95% of the R-waves would be captured without attenuation. The lower frequency cut-
97 off was set to 1 Hz for reasons that are outlined above.

98

99 **LabChart® Analysis of Sections**

100 To analyze the data through the inbuilt ECG analysis in LabChart®, each section was first band-pass
101 filtered using the upper and lower cut-offs. The filtered ECG was then analyzed using the protocol outlined
102 and Fig 1.

103

104 ***Fig 1. Zebrafish larval heartbeats and strategies of the analytical methods. A) Two consecutive larval***

107 ***LabChart® analysis software. Right: The automated analysis protocol that has been implemented in***
108 ***MATLAB***

109

110 The LabChart® software automatically locates the position of each R-wave based on user inputs such as,
111 typical QRS-width, typical RR-interval and QT-interval. Thus the analysis requires some user involvement
112 from the start. After the location has of each heartbeat has been found it is then decided by the user which
113 heartbeats should be deemed ‘acceptable’. This is included in the software so that anomalous or corrupted
114 recording can be omitted from the overall average. In the larval ECG that was studied there were no
115 anomalous beats and so each beat was accepted. This information is then used by the software to produce
116 and average waveform that is produced by finding the mean voltage of the heartbeat at each time point,
117 relative the position of the R-wave.

118 From this average view, the user defines the position of the Q-start point, Q-end point, T-peak and T-end.
119 From this input the software automatically calculates the QTc (based on the Bazett formula) and other
120 heartbeat characteristic. This information was exported as a table into Microsoft Excel for further analysis.
121 Performing the analysis on a section of data takes at least 5 minutes.
122 This process was performed on each section of larval ECG to determine the heartbeat characteristics before
123 and after the introduction of the pharmacological agent.

124

125 *Applying the Automated process*

126 The automated process was applied to each data section and the outputted QTc was then exported to Excel.
127 The program measured the QTc for each 40 consecutive heartbeats and the output was tabulated as shown
128 in Table I.

129

	A	B	C	D	E	F	G	H
QTc 1st 40 beats (s)	0.533	0.525	0.537	0.531	0.544	0.568	0.576	0.563
QTc 2nd 40 beats (s)	0.548	0.523	0.530	0.528	0.522	0.575	0.586	0.564
QTc 3rd 40 beats (s)	0.540	0.522	NA	NA	NA	NA	NA	NA
Average QTc (s)	0.540	0.523	0.533	0.529	0.548	0.572	0.581	0.564
Standard deviation (s)	0.006	0.001	0.003	0.002	0.004	0.004	0.005	0.001
# detected beats	127	125	120	117	104	92	88	86
RR interval (s)	0.472	0.480	0.500	0.513	0.577	0.652	0.682	0.698
QTc change (%)	0.0	-3.1	-1.2	-2.0	1.5	5.9	7.6	4.4

130

131 *Table 1* The outputted data from automated process that has been collated

132

133 The program also generated a plot of the average waveform found for each set of 40 beats, and searched for
134 Q-start, Q-end, T-peak and T-end. These intervals were fed into the Bazett formula to calculate the QTc for
135 each set of beats. An overall QTc for each section of data was found by taking the mean of the measured
136 QTc for each set of beats. The time taken to analyze each section was approximately 10 seconds.

137

138

Results

139 Larval ECG

140 We have previously reported larval ECG capture for characterization of arrhythmia induced by
141 pharmacological agents in zebrafish [5]. By acquiring ECG from these model organisms we are able to
142 evaluate the cardiac effects of drug exposure, temperature changes, anesthetic exposure and staging. A
143 typical larval ECG signal is shown in Fig 1A, above. Furthermore, the ECG offers a high fidelity output of
144 the atrial-ventricular rhythmicity that is responsible for many arrhythmias in humans [6]. We have
145 previously shown that this relationship can be altered in the zebrafish to mimic QTc prolongation in
146 humans by adding cardio-active drugs such as verapamil [5]. However, to analyze the zebrafish ECG we
147 have previously relied on software within the LabChart® suite of programs for collecting
148 electrophysiological data. Although the program is powerful, data analysis is a slow process and requires
149 significant user involvement that potential introduces human error.

150

151 **LabChart® Analysis Software.** LabChart® is a software package offered by AD Instruments to store and
152 analyze electrophysiological measurements that are recorded using PowerLab hardware. The program has a
153 number of inbuilt packages for analyzing ECG data and has previously been used to record and analyze
154 larval zebrafish ECG. LabChart® is used in this work to compare the analysis outputs versus the alternative
155 tools under investigation. The LabChart® ECG analysis package is heavily user-dependent as shown in
156 Fig. 1B. The user must first select a period of ECG that they wish to analyze, specify the RR interval of the

157 data and other characteristics. With this information the software is then able to determine the position of
158 every R-wave within the ECG and attribute a fiducial mark to this time point. The user is then able to select
159 or deselect detected “heart beats” based on their “Isoelectric Noise”, “Form Factor” or “RR-interval”, by
160 setting an acceptable range and domain. Based on the user selections the software then averages all of the
161 accepted heartbeats to produce an average waveform that represents the overall ECG activity for the
162 selected time-period. From this averaged waveform the user determines the position of the P, Q and T
163 features and the software is then able automatically calculate QTc (heartbeat interval corrected for
164 heartrate) and other parameters of the ECG. By performing this process for larval zebrafish ECG before
165 and after drug treatments, it is possible to evaluate any pharmacologically induced alterations in the heart
166 beat cycle. However, this process is time consuming (approximately 3 minutes for 1 data section) and is
167 heavily dependent on the users’ interpretation of the ECG signal.

168

169 **The Automated Analysis Software**

170

171 ***Pan-Tompkins Algorithm for QRS Detection***

172 To build automated signal processing software it is necessary to detect the QRS events of the larval ECG
173 first. Most automated ECG programs attempt to detect the QRS first as it is a dominant feature that is the
174 most robust to change in the cardiac cycle [7]. For this process a program has been developed based on the
175 QRS detection algorithms established by Pan and Tompkins in the 1980’s which have been shown to be
176 robust for many different types of ECG signals [8].

177 The original architecture of the Pan-Tompkins algorithm is divided into three processes which can be
178 thought of as the Initial Learning Phase (ILP), Secondary Learning Phase (SLP), and Detection Phase (DP).

179 The ILP initializes detection thresholds based upon the size of the “signal” and “noise” peaks detected. The
180 SLP uses two full heart cycles to determine the average RR interval and then set the limit of the possible

181 RR-interval for the rest of the ECG trace. To allow for any adaptation of the recorded ECG signal, for
182 example due to pharmacologically induced change in heart rate, these thresholds are adjusted periodically.
183 The DP processes the ECG and generates a pulse for each QRS. It then uses thresholds based on both the
184 filtered ECG and the processed signal to detect the QRS waves. Their detection thresholds were set to just
185 above the “noise” that is sensed by the algorithm. This approach reduced the number of false positives
186 caused by noise that mimics the QRS characteristics, which is always a problem in human ECG due to
187 electromyography artefacts. In zebrafish these artefacts could also be a problem due to sporadic motion
188 artefacts caused by twitching or other motion. The automated process conserves and builds on this
189 architecture.

190 Pan-Tompkins (P-T) used four simple algorithms to process the ECG data and one further algorithm to
191 detect the QRS features from the processed data. These stages can be outlined as:

192 1) Filter the signal to remove artefacts, such as electrical noise at 50 Hz or baseline wander (< 1
193 Hz), and allow the signal to be processed efficiently. In their original work P-T used a transfer function to
194 implement an Infinite Impulse Response Filter (IIR Filter) to remove the artefacts. Unfortunately, these
195 types of filters introduce a phase lag that is proportional to the frequency of the input, and so is undesirable
196 for this work. Instead, for our software inbuilt MATLAB functions are used to filter the signal without a
197 phase lag. The MATLAB code used to implement the filter is shown below. As seen in the code, a `filtfilt`
198 function is employed that applies a 3rd order Butterworth filter to the raw data to band-pass the signal
199 between the upper and lower frequency cut offs that are user defined. The filtered data is then normalized.

200

201 %MATLAB ALGORITHM TO FILTER RAW ECG

202 %Filt_low is user defined cut off to remove low frequency artefacts

203 %Filt_high is user defined cut off to remove high frequency artefacts

204 %ecg_raw is a vector that contains the sampled raw ECG recording

```
205 %FS is the sampling frequency
206 % ecg_filt is the filtered ECG signal
207
    Cut_Win=[Filt_low      % cut off window
    Filt_high]*2/FS;      based on sampling
                           frequency
    N = 3;                 % Order of
                           Butterworth Filter
    [a,b] =                % setup of
    butter(N,Cut_Win);     Butterworth filter
    ecg_filt =             % applying the
    filtfilt(a,b,ecg_raw); filter
    ecg_filt = ecg_h/ max( % normalisation of
    abs(ecg_h));           the signal
```

208

209 2) The second stage of the algorithm is to differentiate the signal to accentuate the turning points. If
210 all artefacts have been removed then the turning points can only be associated with biological events, which
211 for a normal ECG signal occur at the P-wave, R-wave and T-wave. By differentiating, these features
212 become amplified. The amount that they are amplified is proportional to their frequency as higher
213 frequency activity is changing at a faster rate.

Amplification
due to differentiation \propto Frequency of
ECG features

214

215 As R-waves have the highest frequency of the ECG features it is accentuated the most in the differentiated
216 output (Fig 2A).

217

218 The differentiation is applied via the following iteration,

219

$$\varphi_D[T] = \varphi_F[T + 1] - \varphi_F[T]$$

220 Where φ_D is the differentiated output and φ_F is the filtered ECG signal. In MATLAB this can again be
221 applied using an inbuilt function for which the code is given below,

222

223 %MATLAB ALGORITHM TO DIFFERENTIATE FILTERED ECG

224 %ecg_filt is the filtered data from the previous step

225 %ecg_diff is the differentiated output

226 ecg_diff=diff(ecg_filt);

227

228 3) In the thirds stage of the algorithm the differentiated output is squared by applying the iteration,

229

$$\varphi_S[T] = \varphi_D[T] * \varphi_D[T]$$

230 Where φ_S is the squared ECG output. This step further accentuates the turning points in the ECG and
231 makes the signal positive everywhere, as can be seen in Fig. 2A.

232

233 **Fig 2. Graphical representations of the Pan-Tompkins algorithm applied the Larval ECG. A) The**
234 **graphical outputs at each stage of the Pan-Tompkins algorithm, annotation are provided to show the**
235 **position of the R-wave within the signal. B) The result of the Pan-Tompkins algorithm for a 1 minute**
236 **section of data. Shown on the trace are the adaptive signal threshold and noise level utilized by the**

260

261 `ecg_mwi = conv(ecg_sq ,ones(1 ,round(0.150*FS))/round(0.150*FS));`

262

263 5) After the ECG has been processed in this way it is possible to detect the position of the QRS features via
264 a peak-hunting algorithm. Pan-Tompkins developed a dual-threshold technique that adapts to the
265 characteristics of the signal periodically to evaluate the ‘signal’ and ‘noise’ levels in the signal.

266

267 *Pan-Tompkins Adaptive Thresholds*

268 The algorithm first searches through the integrated waveform and an R wave is ‘detected’ every time a
269 peak is found above the established threshold level. If the detected peak is below threshold, it is treated as a
270 noise peak. If an R wave is not detected within 166% of the previously measured RR interval the program
271 performs a search back using the second, lower threshold. Every time a peak is detected the algorithm
272 determines if it is an R-wave using the previously established thresholds and updates the thresholds by the
273 following algorithm:

274 If the peak that has been found is an R-wave then the new running estimate of the R peak height (R_{PK}) is
275 updated as,

$$276 R_{PK} = 0.125*PEAK + 0.875*R_{PK}$$

277 Where PEAK is the height of the detected peak.

278 If the peak that has been found is below threshold and therefore a noise peak, then the new running
279 estimate of the noise peak heights (N_{PK}) is updated as,

$$280 N_{PK} = 0.125*PEAK + 0.875*N_{PK}$$

281 This enables the new thresholds are updated using;

$$282 THRESHOLD_I = N_{PK} + 0.25* | S_{PK} - N_{PK} |$$

$$283 THRESHOLD_{II} = 0.5*THRESHOLD_I$$

284 If a search back is used to find the peak then the new running estimate of the R-peak height is instead
285 updated as,

$$286 R_{PK} = 0.25 * PEAK + 0.75 * R_{PK}$$

287 A sequence of values of R_{PK} and N_{PK} obtained for sections of data of different lengths are shown in Figs.
288 2B and 2C.

289 The program then searches through the filtered ECG signal to find QRS complexes using a similar
290 approach. The program applies thresholds to the filtered ECG in the following way; if the detected peak
291 (FPEAK) is an R-wave then the running estimate of the signal (FR_{PK}) is updated as

$$292 FR_{PK} = 0.125 * FPEAK + 0.875 * FR_{PK}$$

293 If the peak that has been found is a noise peak, then the new noise peak height (FN_{PK}) is updated as,

$$294 FN_{PK} = 0.125 * FPEAK + 0.875 * FN_{PK}$$

295 And again the new thresholds are updated as;

$$296 FTHRESHOLD_I = FN_{PK} + 0.25 * | FS_{PK} - FN_{PK} |$$

$$297 FTHRESHOLD_{II} = 0.5 * FTHRESHOLD_I$$

298 If a search back is used to find the peak then the new running estimate R-peak height is instead updated as,

$$299 FR_{PK} = 0.25 * FPEAK + 0.75 * FR_{PK}$$

300 An identified QRS peak is only declared as an R-wave to be carried forward into the further analysis if it is
301 detected in both passes. Every time a QRS peak is detected there is a 200 ms refractory period in which no
302 other R-wave can be found.

303

304 ***Producing an Average Waveform from the Fiducial Points***

305 Once the Pan-Tompkins algorithm has located the position of each R-wave in a section of ECG they can be
306 used as fiducial points to produce an average waveform, $\bar{\varphi}$. This is found by summing the voltage recorded
307 at equivalent time points, T within each heartbeat, i and then dividing by the number of beats in the

308 average. This enables the mean voltage at every position in the heart beat, relative to the R wave to be
309 determined using the formula below,

310
$$\bar{\varphi}[T] = \frac{\sum_T \sum_{i=0}^N \varphi_i[T]}{N}$$

311 For the automated process the average waveform is calculated for a period that is equal to the measured RR
312 interval that runs from 0.15 s before the R peak. This is shown in Fig. 2D.

313

314 **Detecting ECG features from the Average Waveform**

315 To detect the features from the average waveform the program looks for peaks and troughs in appropriate
316 windows within the heartbeat. The windows are shown in Fig. 2D and correspond to:

317 To find Q the software searches for the local minima in the region that is 0.15 s before the R peak. This
318 window is guaranteed to contain a Q-wave if the R-wave frequency is greater than 6 Hz.

319 To find the T Peak the software searches for the local maxima that has the largest amplitude after the R
320 peak. Once the T-peak has been found the program searches for the next point at which the ECG changes
321 sign and designates this as the T end point. This is in accordance with other well established interpretations
322 of the ECG signal [9].

323

324 **Calculating QTc from the Analyzed Waveform**

325 The QT length is dependent on the heart rate of the fish and so it is necessary to calculate the corrected QTc
326 by feeding in the measured QT and RR interval into the Bazett formula [10], where;

327
$$QTc = \frac{QT}{\sqrt{RR}}$$

328 **Wavelet Transform Analysis**

329 Wavelet transforms allow frequency analysis of a time-dependent signal, which allows the fundamental
330 range of frequencies in the signal to be determined in order to optimize filter selection. The characteristics

```

356 Contour plots of the Wavelet transform of the 20 second section of ECG and a shorter 1s section are shown
357 in Fig. 3, together with the ECG trace on which the transform was performed. As can be seen in Fig. 3A, 42
358 heart beats were recorded in the section and from these beats the R-wave and T-wave frequency could be
359 determined.

```

363 *ECG, and its corresponding wavelet transform. Annotations show the position of the R and T-waves and*
364 *their corresponding frequencies*

```
365
```

366 From the 42 beats the mean characteristic R-wave frequency was found to be, $\overline{R_f} = 24.1$ Hz, with a
367 standard deviation of, $\sigma = 3.4$ Hz. The mean characteristic T-wave frequency was found to be, $\overline{T_f} = 6.6$ Hz
368 , with a standard deviation of 1.3 Hz.

369 Assuming that most of the R-waves are adequately captured when the low pass filter is set to 2 standard
370 deviations above mean frequency, a low pass cut-off of 31Hz was selected for the analysis. It can also be
371 seen that a high pass filter of 1 Hz would not attenuate the signal. As a result of these observations it was
372 decided that the data should be band pass filtered between 1 and 31 Hz to aid further analysis.

373

374 *LabChart® Analysis*

375 Fig. 4 shows a typical outcome of the LabChart® analysis on a section of data. Immediately after the drug
376 is added to the medium the measured QTc decreases which is followed by a steady increase in QTc until
377 around 15 minutes after the drug has been administered. The maximum QTc change measured over this
378 time is just under 5%. There is a steady increase in the RR interval from moment that the drug is
379 administered from a minimum of 0.46 s to a maximum of around 0.7 s.

380

382 *process consists of A) defining the position of each R-wave in the filtered ECG, B) Selecting which beats*
383 *are to be 'accepted' to create C) the average ECG waveform. The average waveform generated for normal*
384 *(before drug) and pharmacologically altered (25 minutes after drug delivery) ECG to highlight the change*
385 *in the QT interval.*

386

387 *The Automated Software Analysis*

388 Our software was able to automatically detect the ECG peaks accurately, and drug effect on Q-T interval
389 was determined (Fig. 5).

390

391 **Fig 5. A comparison of the average ECG before and after 1mM of Verapamil had been added to the**
392 **recording media.** The top waveform produced from ECG 1 minute before the drug had been introduced,
393 the bottom figure was taken from data 20 minutes after the drug had been introduced.

394

395 The measured QTc and RR interval from the automated analysis have been plotted in Fig. 6.

396

397 **Fig 6. Scatter Graph to show the measured QTc and RR interval for the larvae from the MATLAB**
398 **Software.**

399

400 In the same way that was demonstrated by the LabChart® analysis software, immediately after the drug is
401 added to the medium the measured QTc decreases which is followed by an increase in QTc until around 15
402 minutes after the drug has been administered. However, for this analysis software the maximum QTc
403 change measured over this time is just under 8%. It can also be seen that again there is a steady increase in
404 the RR interval from moment that the drug is administered that is almost identical to the LabChart®
405 analysis software (Fig. 7).

406

407 **Fig 7. Scatter Graph to show the measured QTc and RR interval for the larvae from the LabChart®**
408 **Software.**

409

410 *Comparison of the LabChart® and MATLAB analysis software*

411 To aid comparison between the two analysis techniques the LabChart® and automated data are plotted
412 together in Fig. 8. As can be seen in Fig. 8A, the measured QTc initially start off very similar until around 7
413 minutes after the drug has been added, after which the automated MATLAB software consistently records a

414 higher QTc than the LabChart® program. This phenomena occurs despite the programs measuring a very
415 similar RR interval and detected number of beats for each section. The difference between the two analysis
416 techniques is further illustrated in Fig. 8D, which shows the measured QTc change for both. Although the
417 patterns are broadly similar, the automated process consistently records larger QTc change than the
418 LabChart® program.

419

422 *detected beats, D) comparison of measured QTc change for both programs.*

423

424

425

Discussion

426 The automated process is a significant improvement on the approaches that were previously applied to the
427 zebrafish ECG. This article shows that the automated process that is based on established techniques of
428 analyzing ECG can sensitively measure pharmacologically induced changes in the ECG.

429 However, it has also been shown that there are differences between the results obtained through the
430 analysis with the LabChart® software and the automated process. The main difference is that the automated
431 process consistently measures a larger QTc change that the previously used approach. This can be
432 explained by the fact the LabChart® program analyses the whole section in one go, compared to the
433 automated the process that outputs the QTc value for each 40 beats. Assuming that the QTc is not constant
434 within each section of the ECG recording, the LabChart® software will be less sensitive to subtle variations
435 in the ECG as it instead finds a global average across the whole section. Even if QTc at the start and the
436 end of the section are systematically different, the overall result will be somewhere in the middle. Instead,

437 by focusing on smaller numbers of beats within the section the automated process provides a truer
438 reflection of the actual QTc change within the recording and is more able to pick up these smaller changes.

439 The automated process is faster is able to detect the heart beats robustly and has less human
440 involvement than the LabChart® software, so it represents a significant improvement in the analysis
441 available when analysis zebrafish larval ECG. Furthermore, there is no reason why this software cannot be
442 applied to human ECG in the same way.
