29   Running title: Gliding machinery of *Mycoplasma mobile*

30   Keywords: F_1-ATPase, rotary motor, parasitic bacteria, electron microscopy, atomic

31   force microscopy, bacterial motility

32   **ABSTRACT**

33   *Mycoplasma mobile*, a fish pathogen, exhibits gliding motility using ATP hydrolysis

34   on solid surfaces, including animal cells. The gliding machinery can be divided into

35   surface and internal structures. Interestingly, the internal structure of the probable

36   gliding motor has 28 protein chains, each of which has 17 particles composed of

37   homologs of the catalytic α- and β-subunits of F_1-ATPase. In this study, we isolated

38   chain particles and determined their structures using negative-staining electron

39   microscopy and high-speed atomic force microscopy. The isolated chain particles

40   were composed of five proteins, MMOBs 1660 (α-subunit homolog), 1670

41   (β-subunit homolog), 1630, 1620, and 4530, and showed ATP hydrolyzing activity.

42   The 2D structure, with dimensions of 35 and 26 nm, showed a hexameric ring dimer

43   about 12 nm in diameter, resembling F_1-ATPase catalytic $(αβ)_3$. We isolated the

44   F_1-like ATPase unit, which is composed of MMOBs 1660, 1670, and 1630.

45   Furthermore, we isolated the complex in chain form and analyzed the 3D structure,

46   showing that dimers of mushroom-like structures resembling F_1-ATPase were

47   connected and aligned along the dimer axis at 31 nm intervals. An atomic model of

48   F_1-ATPase catalytic $(αβ)_3$ from *Bacillus* PS3 was successfully fitted to each

49   hexameric ring of the mushroom-like structure. These results suggest that the motor

50   for *M. mobile* gliding shares an evolutionary origin with F_1-ATPase. Based on the

51   obtained structure, we propose possible force transmission processes in the gliding

52   mechanism.

53

54 **IMPORTANCE**

55 F_1F_o- ATPase, a rotary ATPase, is widespread in the membranes of mitochondria,

56 chloroplasts, and bacteria, and converts ATP energy with a proton motive force

57 across the membrane by its physical rotation. Homologous protein complexes play

58 roles in ion and protein transport. *Mycoplasma mobile*, a pathogenic bacterium, was

59 recently suggested to have a special motility system evolutionarily derived from

60 F_1-ATPase. The present study isolated the protein complex from *Mycoplasma* cells

61 and supported this conclusion by clarifying the detailed structures containing

62 common and novel features as F_1-ATPase relatives.

INTRODUCTION

63

64   Mycoplasmas are parasitic bacteria characterized by small cell size, a short

65   genome and lack of a peptidoglycan layer (1-3). Many *Mycoplasma* species exhibit

66   a unique gliding motility, which is necessary for their infection (4-6). *Mycoplasma*

67   *mobile* glides on solid surfaces at 2.0 to 4.5 µm/s in the direction of a protrusion on

68   one side of the cell (Fig. 1A) (5). The gliding machinery is localized to the cell

69   protrusion and can be divided into surface and internal structures (Fig. 1B, upper).

70   The surface structure has approximately 450 repeats of a complex of three large

71   proteins, Gli123, Gli521, and Gli349, inserted into the cell membrane (Fig. 1B,

72   lower) (7-11). Fifty-nm-long leg structures corresponding to Gli349 molecules can

73   be seen jutting out from cell protrusion by electron microscopy (EM) (12). The tip of

74   Gli349 is characterized by a "foot" with an oval structure that can bind to sialylated

75   oligosaccharides (SOs) (13-20). Gli521 and Gli123 serve as the "crank" that

76   transfers force to Gli349 and the "mount" that localizes the other two surface

77   proteins to the gliding machinery, respectively. A working model of the gliding

78   mechanism has been proposed in which the cells are propelled by Gli349 molecules

79   that repeatedly catch, pull, and release SOs on solid surfaces (5, 21-23).

80   The internal structure consists of a lumpy structure at the tip of the cell

81   protrusion and 28 "chains" lining the inner membrane surface (Fig. 1B) (23-26).

82   Each chain is characterized by 17 repeating particle structures, resulting in a total of

83   476 particles in one cell. The internal structure consists of least ten proteins (Fig.

84   1C). Six of these proteins, MMOBs 1620, 1630, 1640, 1650, 1660 and 1670 were

85   coded tandemly in a locus. Interestingly, MMOBs 1660 and 1670, which have

86   Walker A and B motifs that are involved in ATP binding and hydrolysis (27), show

87   high amino acid sequence identity with the catalytic subunits α and β of F_1-ATPase,

88   respectively. MMOB1670 has an extra N-terminal region (amino acids 1–299),

89   which is not present in the β subunit.

90   F_1F_o-ATPases, found in most organisms, are rotary motors that perform

91   biological energy conversion (28, 29). Their role is to both synthesize ATP using a

92   proton motive force and, conversely, to hydrolyze ATP to drive protons to maintain

93   the membrane potential. Their structure is composed of a soluble catalytic

94   F_1-domain for ATP catalysis and a membrane-embedded F_o-domain for the proton

95   pathway. In the F_1-domain, the catalytic subunits α and β alternate to form a

96   hexameric ring $(αβ)_3$ that rotates the central stalk penetrating the ring using ATP

97   hydrolysis. Phylogenetic studies have shown that *Mycoplasma* have three F_1-like

98   ATPase clusters, which are referred to as Type 1–3 ATPases (26, 30). Type 1, found

99   in all mycoplasmas, is a typical operon encoding F_1F_o-ATPase and is likely to

100   function as a proton pump to maintain membrane potential. Type 3 is found in

101   mycoplasmas that have an MIB-MIP system to cleave host immunoglobulins (31).

102   Type 2 is only found in four *Mycoplasma* species, including *M. mobile*. Interestingly,

103   the Type 2 ATPase of *M. mobile*, which encodes MMOB1620–70, is involved in the

104   internal structure of the gliding machinery.

105   Recently, the chains of the internal structure were shown to have structural

106   changes linked to ATP hydrolysis, suggesting that they drive gliding motility (23, 32).

107   However, it is still unclear how the chain generates and transmits the force to the

108   outside, because its detailed structure has not been clarified. In this study, we

109   isolated the chains and their component particles and elucidated their structures.

110   The structure had a common architecture with F_1-ATPase, suggesting that the chain

111   shares a common evolutionary origin with F_1-ATPase. Based on our findings, we

112   suggest two possible force transmission models for the gliding machinery.

113

114   **Results**

115   **Isolation and biochemical analyses of chain particles.** To examine the

116   solubility of the chain particles, we lysed cultured *M. mobile* cells with 1% Triton

117   X-100 and recovered the insoluble fraction by centrifugation (24). We then

118   suspended the insoluble fraction with buffers containing various concentrations of

119   NaCl and examined the solubility of the chain particles by centrifugation (Fig. S1).

120   Approximately ten proteins were solubilized in NaCl at concentrations of 137 mM

121   and higher, including MMOB1670, which is known to be a component of the chain

122   (24). Based on this observation, we isolated the chain particles from *M. mobile* cells

123   as follows: We suspended the Triton-insoluble fraction of *M. mobile* cells in a buffer

124   containing 137 mM NaCl to solubilize the chain particles free of contaminating

125   proteins. The soluble fraction recovered by centrifugation was then subjected to

126   Superdex 200 gel filtration chromatography. The peak fraction in the void contained

127   MMOBs 1620, 1630, 1660, and 1670, which are coded on the mycoplasma Type 2

128   ATPase operon, and MMOB4530 annotated as phosphoglycerate kinase (PGK)

129   (Fig. 2A). These proteins are known to be components of the internal structure (Fig.

130   1C) (23-26). To examine the assembly of these proteins, we applied the isolated

131   fraction to gel filtration chromatography using a Sephacryl S-400 HR column, which

132   can fractionate up to 8000 kDa globular proteins (Fig. 2B). The proteins eluted as a

133   single peak at a non-void position and were larger than 669 kDa, suggesting that

134   they form a large complex. The molar ratios of the components were estimated to

135   be 3.2:2.9:3.0:1.0:2.3 for MMOBs 1670, 4530, 1660, 1630, and 1620, respectively,

136   from the relative intensity of the SDS-PAGE bands stained by Coomassie brilliant

137   blue (CBB). We then analyzed the isolated fraction by blue-native (BN) PAGE (Fig.

138   2C, left). A single band was detected at approximately 1000 kDa, which is

139   consistent with the gel filtration chromatography results. Next, we applied the band

140   to an In-gel ATPase activity assay, which detects the activity as a white precipitation

141   of lead caused by released of inorganic phosphate (Fig. 2C, right). The band with

142   the complex showed precipitation, indicating ATPase activity. In addition, we

143   assayed the isolated fraction for phosphate release from solution. The complex

144   hydrolyzed ATP at a maximum turnover rate of 0.18 molecules/s per MMOB1670

145   subunit, β-subunit paralog with a K_m of 74 µM at 25°C (Fig. 2D). The ATPase activity

146   was inhibited by addition of 15.4 mM sodium azide, an inhibitor to ATPases with

147   Walker A motifs (33), with a K_m of 108 µM and a maximum turnover rate of 0.055

148   molecules/s. In a previous study, the Triton-insoluble fraction, which included the

149   internal structure, showed ATPase activity with a K_m of 66 µM and a maximum

150   turnover rate of 0.09 molecules/s and was suppressed by 15.4 mM sodium azide,

151   showing a K_m of 84 µM and a maximum rate of 0.063 molecules/s (23). The values

152   obtained here are comparable to these previous data. The above results suggest

153   that the chain particle is the motor in the internal structure of the gliding machinery.

154   **Hexamers resembling F_1-ATPase catalytic $(αβ)_3$ form a dimer.** We observed

155   the isolated chain particles by EM using the negative-staining method. A field image

156   showed uniform particles with axes of 20 and 40 nm (Fig. 3A and B). As the particle

157   frequency depended on the protein concentration, we concluded that the observed

158   particles were a part of the protein complex. We picked 2148 particle images

159   automatically using RELION software (34) for 2D-classification. From the

160   2D-classification in 100 classes, we obtained four clear particle images (Fig. S2).

161   We adopted mirror images according to the structure observed in high-speed

162   atomic force microscopy (HS-AFM) (see below). Structural handedness cannot be

163   judged from EM images because they are projections of electrons transmitted

164   through the sample. We focused on an image showing a complex structure with

165   dimensions of 35 and 26 nm featuring nearly two-fold symmetry (Fig. 3C and D).

166   Interestingly, the characteristic hexamer of about 12 nm in diameter formed a dimer

167   and was reminiscent of F_1-ATPase catalytic $(αβ)_3$. Considering that the amino acid

168   sequences of MMOBs 1660 and 1670 have high identity to the α- and β-subunits of

169   F_1-ATPase, respectively, the dimeric complex is probably evolutionarily related

170   F_1-ATPase. The distance between the centers of the two hexamers was 11.0 nm.

171   The complex had ten filamentous structures around the two hexamers, four of which

172   appeared to form bridges across the two hexamers. Hereafter, we refer to this

173   structural unit as the "motor."

174   **The hexamer featured a ring and a peak.** Next, we visualized the motor using

175   HS-AFM to clarify the structure under liquid conditions. HS-AFM is a powerful

176   method that can visualize the structure and dynamics of single molecules in liquid

177   conditions at a video rate (35, 36). In this method, a specimen is placed on the

178   stage surface and with a probe is scanned in buffer at high speed. In this study, we

179   placed the isolated motor on a mica surface and scanned it in an area of 70 × 70

180   nm^2 at 56 × 56 pixels with a scanning rate of 100 ms per frame. HS-AFM images

181   showed a complex with dimensions of approximately 30 and 20 nm composed of

182   two globules and attached by 2–4 lateral protrusions shorter than 15 nm (Fig. 3E;

183   Movie S1 and S2). The molecular images were categorized into two patterns as

184   either a ring (pattern I) or a peak (pattern II), based on the central part. Then, we

185   observed them at a higher resolution (area, 40 × 40 nm^2 with 50 × 50 pixels;

186   scanning rate, 100 ms per frame) (Fig. 3F). In pattern I, the slice image near the top

187   end of the motor between 9.8 and 11.3 nm above the substrate surface showed two

188   hexameric rings (Fig. 3G). The position and direction of the two rings in the dimer

189   are consistent with those of the hexamers in the negative-staining EM image. In

190   addition, the distance between the centers of the two hexameric rings was 10.4 nm

191   (Fig. 3H), in agreement with the distance between the centers of the hexamers in

192   the negative-staining EM image (Fig. 3C). These observations suggest that the

193   shape of the motor structure in liquid is preserved in negative-staining EM

10

194   conditions and that the hexamers form rings like F_1-ATPase catalytic $(\alpha\beta)_3$. In

195   pattern II, the two central peaks were positioned 11.2 nm apart (Fig. 3H, lower),

196   similar to the distance between the centers of the hexameric rings in pattern I (Fig.

197   3H, upper), suggesting that patterns I and II are two sides of the same coin (Fig. 3E,

198   left). Interestingly, in most of the particles, the two peaks at 6 and 5 nm became

199   invisible in 20 s, between frames 1 and 3 (Fig. 3I and J; Movie S3). We concluded

200   that these subunits dropped out because they did not reappear until the complex

201   was disrupted. Next, we focused on the lateral protrusions of these particles. To

202   visualize them more clearly, we scanned the motor by HS-AFM with an area of 120

203   × 120 nm^2, 120 × 120 pixels, and scanning rate 500 ms per frame. The motor

204   showed seven lateral protrusions around the two globules (Fig. 3K). These

205   protrusions swayed without being fixed (Fig. 3L; Movie S4).

206   **Isolation of F_1-like ATPase unit.** Next, we treated the isolated motors with

207   1.5% sodium cholate, an anionic detergent. BN-PAGE and In-gel ATPase activity

208   assays showed a single band with ATPase activity at a position lower than the

209   original one, corresponding to 720–1048 kDa, indicating that the motor dissociated

210   into smaller units with ATPase activity (Fig. 4A). To isolate the ATPase unit, we

211   applied the motor treated with 1.5% sodium cholate to Sephacryl S-400HR gel

212   filtration chromatography. The elution pattern showed at least five continuous peaks

213   with broad peaks (Fig. 4B). The three peaks at elution volume 80–100 mL were 2–4

214   times larger than those of the other two peaks. These large peaks are thought to be

215   formed by more than 20 different proteins, as shown by the reverse-stained

216   SDS-PAGE gel (Fig. S3). These proteins are probably rich in tryptophan and

217   tyrosine residues because the absorbance at 280 nm wavelength was monitored

218   during gel filtration. A CBB-stained SDS-PAGE gel showed that MMOBs 1670, 1660,

219   and 1630 eluted in the same fractions, while MMOBs 4530 and 1620 eluted at later

220   fractions (Fig. 4C), indicating that MMOBs 4530 and 1620 were dissociated from the

221   motor by sodium cholate treatment.

222   We focused on the F6 fraction, which mainly contained MMOBs 1670, 1660,

223   and 1630 (Fig. 4D). This complex corresponds to the BN-PAGE band showing

224   ATPase activity (Fig. 4A), because only MMOBs 1660 and 1670 have the Walker A

225   and Walker B motifs in the motor components. EM observation using the

226   negative-staining method showed uniform globular particles 10–15 nm in diameter

227   (Fig. 4EF). As the particle frequency depended on the protein concentration, we

228   concluded that the observed particles were a part of the protein complex. We picked

229   11687 particle images automatically using RELION software for 2D-classification.

230   By 2D-classifing the images in 50 classes, we obtained 15 clear particle images,

231   which were averaged (Fig. S4). Fig. 4G shows a 12 nm diameter globule

232   characterized by a single hexameric ring, corresponding to a part of the motor

233   image in Fig. 3C. Three of the subunits were larger than the others with hook

234   structures on either side of the edge. Three averaged images (II–IV) showed a

235   mushroom-like structure resembling F_1-ATPase, which is characterized by a 12

236   nm-diameter umbrella and a 3 nm-long stalk (Fig. 4G). These observations suggest

237   that MMOBs 1670, 1660, and 1630 form an F_1-like ATPase unit. MMOB4530 was

238   probably not included in this unit because it probably binds to the complex and

239   could not be distinguished in the image due to the low proportion of bound entities

240   (Fig. 4D). Thus, the hexameric ring is likely formed by the α-subunit homolog

241   MMOB1660 and the β-subunit homolog MMOB1670, and the stalk is formed by

242   MMOB1630.

243   **Motor chain structure.** In gliding machinery, motors link to form chains. To

244   isolate the chain, 387 mM NaCl was added to the Triton-insoluble fraction from *M.*

245   *mobile* cells. We then applied this fraction to gentle mixing and centrifugation at

246    $5000 \times g$ for 5 min, milder conditions than that for motor (chain particle) isolation.

247   The supernatant contained more than 20 proteins, including the motor component

248   proteins MMOBs 1670, 4530, 1660, 1630, and 1620 as major components (Fig. 5A).

249   EM observation using the negative-staining method showed chain structures with

250   lengths longer than 70 nm and particles of various sizes (Fig. 5B and C). This time

251   we manually picked 2127 particles from the chain images using RELION software,

252   overlapping approximately 50% of the 71×71 nm^2 box area. From 2D-classifcation

253   in 20 classes, we obtained seven clear particle images (Fig. 5D). The particle

254   images show the various orientations required for 3D reconstruction. We then

255   created a 3D map by combining a total of 1709 particle images of good quality (Fig.

256   5E and S5). The 3D map with dimensions of 70, 20, and 15 nm at a density

257   threshold (contour level = 0.026) was composed of two dimers of mushroom-like

258   structures resembling F_1-ATPase, aligned along the dimer axis (Fig. 5E). The

259   dimers were connected by a bulge structure with a diameter of 5 nm. The chain

260   interval was 31 nm, consistent with the corresponding dimension in a 2D image

261   from electron cryotomography (ECT) (23), suggesting that the 3D model obtained

262   reflects the original structure from a cell. The mushroom-like structure with a

263   diameter of 15 nm, consisting of a hexameric ring and a central stalk, was

264   connected to the dimer by two bridge structures with a diameter of 3–6 nm. An

265   atomic model of F_1-ATPase catalytic $(\alpha\beta)_3$ from *Bacillus* PS3 (PDB ID 6N2Y) (37)

266   was fitted into each hexameric ring of the mushroom-like structure (Fig. 5F). The

267   distance between the centers of the fitted $(\alpha\beta)_3$ in the dimer was 12.5 nm, which is

268   in agreement with that of the motor observed by negative-staining EM and HS-AFM

269   (Fig. 3C and H). The fitted model showed that each hexameric ring had two

270   protrusions of 3–6 nm pointing laterally (Fig. 5F). The cross-sections of each

271   mushroom-like structure showed the central stalk length of 5 nm (Fig. 5G). A cavity

272   was observed at the center of the hexameric ring. However, it may be an artifact of

273   the low-resolution map of negative-staining EM, because metal coating tends to

274   emphasize the peripheral part of large particles (38). Next, we compared a

275   reprojection image of the 3D chain map with the 2D averaged image of the motor

276   from negative-staining EM (Fig. 5H). Two short filaments marked by asterisks in the

277   dimer (Fig. 5H, left) are positioned facing each other in the connecting bulge (Fig.

278   5H). Previously, electron cryotomography (ECT) of a permeabilized *M. mobile* cell

279   showed a chain structure characterized by repeats of two globules and two types of

280   projections to the cell membrane (Fig. 5I, left) (23). The hexameric ring and the

281   central stalk in the 3D map here correspond to the globule and one type of

14

282   projection to the cell membrane in the ECT image, respectively, suggesting that the

283   chain is oriented with the central stalk facing the membrane, which is common in

284   F_1-ATPases. At the interface between the motors, the 3D map here did not include a

285   structure composed of another type of projection and a globule as observed in the

286   ECT image. The subunits corresponding to these structures probably had structural

287   variations or dissociation during the isolation process.

288

Discussion

290   **Outline of internal structure of gliding machinery.** Previously, sequence

291   analysis suggested that the chain of *M. mobile* gliding machinery evolved from

292   F_1-ATPase (5, 23-26). The present study supports this conclusion by structural data

293   showing that the chain has hexameric rings similar to the F_1-ATPase catalytic $(\alpha\beta)_3$.

294   Integrating available information, we can now describe the outline of the internal

295   structure of *the M. mobile* gliding machinery (Fig. 1B). *M. mobile* cells have 28

296   individual 530 nm long chains, each of which contains 17 motor units composed of

297   two F_1-like ATPases and filamentous structures (23). The central stalk of the F_1-like

298   ATPase and another protrusion from the connecting bulge project to the cell

299   membrane.

300   **Unique role of F_1-ATPase related complex.** To date, several complexes are

301   known to be evolutionarily related to F_1-ATPase, all of which are responsible for

302   transporting substances across the membrane (39). However, the motor we

15

303   identified here most likely plays a role in motility. This case may be reminiscent of

304   dynein, a motor in eukaryotes, which evolved from a widely conserved AAA

305   (ATPases associated with diverse cellular activities)+ protein, in which multiple

306   subunits of ATPases perform functional rotation (40, 41). Sequence analyses have

307   shown that mycoplasma Type 3 ATPase is also related to F_1-ATPase, and its role

308   has been suggested to promote substrate turnover in the MIB-MIP system (31). If

309   Type 3 ATPase provides the force to change the conformation of a hydrolytic

310   enzyme, its role in force generation is common with Type 2, the gliding motor.

311   F_1F_o-ATPases are known to be dimerized through interactions between

312   F_o-domains and are usually arranged in rows along the short axis in the tightly

313   curved cristae ridges of mitochondria (29, 42, 43). The dimer structure found in the

314   present study is not related to this, because the F_1-like domain is dimerized through

315   the filament structure and is linked in the long axis direction. However, some roles

316   may be common in part if the dimerization and chain formation observed in the

317   gliding motor identified in this study stabilizes the membrane structure, as seen in

318   the F_1F_o-ATPase dimer (44). Moreover, dimerization may result in cooperativity in

319   motor functions. The gliding motor here is mostly a two-rotational symmetrical

320   structure, whereas gliding occurs unidirectionally. The directionality may be

321   provided by the surface part of the gliding machinery rather than the gliding motor

322   itself. In fact, the binding of cells to sialic acids is known to have directionality, which

323   is probably provided by the foot of Gli349 (14, 16, 45).

324   **Protein assignment.** The α-subunit homolog MMOB1660 (58.7 kDa) and the

16

325   β-subunit homolog MMOB1670 (88.4 kDa) likely correspond to the smaller and

326   larger subunits, respectively, of the hexameric ring of an F_1-like ATPase unit, as

327   suggested by the estimated 1:1 molar ratio in the motor (Fig. 2B). This means that

328   the hook structure of the larger subunit may be formed by the extra N-terminal

329   region (34.8 kDa) of MMOB1670. Previously, 3D structure modeling based on

330   secondary structure suggested that MMOB1630 is structurally similar to the γ

331   subunit, the principal component of the central stalk of F_1-ATPase (5). In general,

332   the γ subunit of F_1-ATPase is composed of a coiled-coil and a globular domain and

333   penetrates the hexameric ring (46). In the F_1-like ATPase unit and chain 3D model,

334   a stalk structure, suggesting the globular domain of the γ subunit, was found in the

335   center of the hexameric ring (Fig. 4G and 5G), implying that MMOB1630 penetrates

336   the hexameric ring like the γ subunit.

337   Using HS-AFM observations, the peak at approximately 5 nm at the center of the

338   hexameric ring dropped out with time (Fig. 3I). The peak height agrees with the

339   length of the estimated globular domain of MMOB1630 in the chain 3D model (Fig.

340   3J and 5G), suggesting that the peak is composed of MMOB1630 and was pulled

341   out from the hexameric ring by the scanning cantilever during HS-AFM observation.

342   The pull-out event is thought to be common to that of the F_1-ATPase, in which the γ

343   subunit is removed from the hexameric ring by optical tweezers (47).The

344   filamentous structures around the hexameric ring probably correspond to lateral

345   protrusions in the HS-AFM images and are formed by the remaining proteins,

346   MMOB1620 and MMOB4530 (PGK). These proteins probably play roles in ATPase

17

347　dimerization, chain formation, and chain bundling (23). MMOB1620 is an

348　unannotated protein specific to the Type 2 ATPase cluster (26, 30). MMOB4530 is

349　annotated as an enzyme that transfers phosphate groups from

350　1,3-bisphosphoglycerate to ADP in glycolysis to yield ATP and 3-phosphoglycerate

351　(48). In *M. mobile*, ATP is probably provided by glycolysis (49). MMOB4530 may

352　supply ATP efficiently to the gliding motor by its close proximity. Yeast V-ATPase,

353　which belongs to the rotary ATPase family like F_1F_o-ATPase, is also attached by two

354　glycolytic enzymes, 6-phosphofructo-1-kinase and aldolase (50-52). These

355　glycolytic enzymes are involved in the regulation of V-ATPase assembly and

356　activity.

357　**Possible force transmission mechanisms for gliding.** The involvement of an

358　internal ATPase in the gliding mechanism is based on the following five

359　observations from the analysis of the "gliding head" of *M. mobile* protrusions and of

360　the isolated gliding machinery: (a) The affinity for ATP is comparable in the ATPase

361　activity of the internal structure and the speed of the gliding head (23). (b) Substrate

362　binding and gliding speed of the gliding head are inhibited by azide, as well as the

363　ATPase activity of the internal structure (23). (c) The chain in the internal structure

364　undergoes conformational changes based on ATP hydrolysis (23, 32). (d) Among

365　the 21 proteins identified from the gliding head, only MMOBs 1660 and 1670 could

366　be suggested for ATPase from the amino acid sequences alone (23, 24). (e)

367　Fluorescent protein tagging of components of the internal structure significantly

368　affects the binding activity and gliding speed of *M. mobile* cells (26).

18

369   The structure elucidated in the present study allows us to discuss the gliding

370   mechanism in more detail. In F_1-ATPase, the three catalytic sites in the hexameric

371   ring cooperatively hydrolyze ATP, and each catalytic β-subunit undergoes a bending

372   motion that drives the rotation of the central stalk (46). Previously,   structural

373   changes linked to ATP hydrolysis were reported: (I) EM studies showed 2 nm

374   contraction of particle intervals in the isolated chains (23), and (II) HS-AFM studies

375   showed movements of individual motors in the cell 9 nm perpendicular to the chain

376   long axis and 2 nm into the cell (32). Considering these observations, we propose

377   two different working models for the force transmission mechanism in gliding (Fig.

378   6). In the "contraction model" (Fig. 6 i), the force generated by the hexameric ring

379   shortens the chain. The resulting displacement of the projections from the motor to

380   the cell membrane drives the hook structure of Gli521 like a "lever." Then, the leg

381   moves with the catch, pull, and release of the SOs. In the "rotation model" (Fig. 6 ii),

382   the force generated by the hexameric ring rotates MMOB1630 in the same way as

383   F_1-ATPase. This rotation is transmitted across the cell membrane to the Gli521. The

384   hook structure converts rotational motion into linear motion of the leg, similar to a

385   crank. Previous studies have reported that *M. mobile* exhibits unitary steps of

386   approximately 70 nm in size at no load (53, 54). In our models, both the rotation and

387   contraction displacements are expected to be a few nanometers. These

388   displacements may be amplified by the large surface structure complex formed by

389   the 100 nm long Gli349 and 120 nm long Gli521, which show dimensions

390   comparable to the step size, acting as a large gear (22). This conjecture could

19

391   explain how a single leg exerts a force of 1.5 pN, smaller than that of conventional

392   motor proteins such as myosin, dynein, and kinesin.

393   **Evolution of *M. mobile* gliding.** A previous study suggested that Gli349 evolved

394   from a static binding receptor to parasitize the host (16). Considering this, the

395   evolutionary origin of *M. mobile* gliding can now be discussed. F_1F_o-ATPase, which

396   is abundant on the cell membrane, could have been accidentally associated with

397   the binding receptor and turned into a primitive motility system, which may have

398   provided random cell spreading. The system was then refined under survival

399   pressure, because motility might be beneficial to infection and evading the host's

400   immune system. For dimerization and chain formation, PGK was then incorporated

401   into the gliding machinery, because PGK was working in close proximity to

402   F_1F_o-ATPase.

403

404   **Materials and Methods**

405   **Strains and culture conditions.** We used P476R *gli521*, a mutant strain of *M.*

406   *mobile* that can glide normally but binds SOs more tightly than wild-type strains (10,

407   22, 55). *M. mobile* cells were cultured as described previously (56, 57).

408   **Optical microscopy.** The cultured cells were inserted into a tunnel chamber

409   assembled with two coverslips and double-sided tapes and observed by

410   phase-contrast microscopy using an inverted microscope (IX71; Olympus, Tokyo,

411   Japan) (17, 19). Movement was recorded using a complementary metal-oxide

412   semiconductor (CMOS) camera (DMK33UX174; The Imaging Source, Bremen,

413 Germany). Video was analyzed using the ImageJ software, version 1.53a

414 (http://rsb.info.nih.gov/ij/).

415 **Chain particle isolation.** All procedures were performed at 4°C unless

416 otherwise noted. To investigate the solubility of the chain particle, *M. mobile* cells

417 from 60 mL of culture medium were collected by centrifugation at 14000 × g for 20

418 min and washed twice with PBS consisting of 8.1 mM Na_2HPO_4, 1.5 mM KH_2PO_4,

419 pH 7.3, 2.7 mM KCl and 137 mM NaCl. Cells were resuspended in PBS to a 12-fold

420 higher concentration than the culture and sonicated for 1 min at 24–27°C to be

421 dispersed in microtubes using an ultrasonic generator (2510 J-MT; BRANSON,

422 Kanagawa, Japan). The cells were then treated with Triton solution (1% Triton

423 X-100, 0.1 mg/mL DNase, 5 mM $MgCl_2$, and 1 mM phenylmethylsulfonyl fluoride in

424 PBS) in a total volume of 10 mL. After gentle shaking for 30 min, the suspensions

425 were centrifuged at 20000 × g for 20 min, and pellets were collected and washed

426 once with suspension buffer, PBS with 5 mM $MgCl_2$. Pellets were then resuspended

427 in suspension buffer with 0 to 400 mM NaCl by pipetting several times. After

428 overnight treatment, suspensions were centrifuged at 20000 × g for 20 min, and

429 supernatants and pellets collected for SDS-PAGE analysis.

430 For isolation of chain particles, *M. mobile* cells from 1.2-liter cultures were

431 collected by centrifugation at 14000 × g for 30 min and washed three times with

432 PBS. The cells were resuspended in PBS to a 100-fold higher concentration than

433 the culture and sonicated for 1 min using an ultrasonic generator at 24–27°C. The

434 cells were treated with 0.05 mg/mL RNase in Triton solution in a total volume of 207

435   mL. After 1 h of gentle shaking, the suspension was centrifuged at 20000 × g for 20

436   min, and pellets were washed once with suspension buffer. Pellets were then

437   resuspended in suspension buffer by pipetting up and down and allowed to dissolve

438   overnight. The soluble fraction was collected by centrifugation at 20000 × g for 20

439   min and loaded onto a HiLoad 16/600 Superdex 200 column (Cytiva, Tokyo, Japan)

440   equilibrated with 1 mM $MgCl_2$ in PBS at a flow rate of 0.8 mL/min. The fractions

441   were analyzed by SDS-PAGE and CBB staining. Focused protein bands were

442   identified by PMF, as previously reported (24, 58), and the chain particle fraction

443   was recovered.

444   We modified this procedure to isolate the F_1-like ATPase unit. The washed $M.$

445    $mobile$ cells were treated with Triton solution in a total volume of 207 mL. After 1 h

446   of gentle shaking, the suspension was centrifuged at 20000 × g for 20 min, and the

447   pellet was washed once with suspension buffer. The pellet was suspended in 20

448   mM Tris-HCl (pH 7.5), 250 mM NaCl, 1 mM phenylmethylsulfonyl fluoride, and 1

449   mM $MgCl_2$ with pipetting as before and allowed to dissolve overnight. The soluble

450   fraction was collected by centrifugation at 20000 × g for 20 min and mixed with 2%

451   (w/v) sodium cholate. After 7 h of incubation, the complexes were loaded onto a

452   Sephacryl S-400 HR column (Cytiva) equilibrated with 0.7% sodium cholate, 20 mM

453   Tris-HCl (pH 7.5), 250 mM NaCl, and 1 mM $MgCl_2$ at a flow rate of 0.5 mL/min. The

454   elution curve was fitted using Igor Pro 6.34j (WaveMetrics, Lake Oswego, OR, USA).

455   The fractions were analyzed by SDS-PAGE and CBB- and reverse-staining (59, 60).

456   The fraction of the complex composed of MMOBs 1670, 1660, and 1630 was

22

457 collected. Samples were concentrated using an Amicon Ultra 100 K spin filter

458 (Merck KGaA, Darmstadt, Germany), if necessary.

459 **Isolation of chain.** All procedures were performed at 4°C. *M. mobile* cells from

460 15 mL of culture medium were collected as a pellet by centrifugation at 14000 × *g*

461 for 25 min and washed twice with PBS. Cells were resuspended in PBS to a

462 100-fold higher concentration than the culture and sonicated for 1 min at 24–27°C in

463 microtubes using an ultrasonic generator. The cells were then treated with Triton

464 solution as above in a total volume of 300 µL. After gentle shaking for 30 min, the

465 suspension was centrifuged at 20000 × *g* for 20 min, and the pellet containing the

466 internal structures was resuspended in suspension buffer. The suspension was then

467 gently mixed with an equal volume 500 mM NaCl in suspension buffer. The chain

468 was recovered as the supernatant by centrifugation at 5000 × *g* for 5 min.

469 **Analytical gel filtration.** The isolated chain particle solution was loaded onto a

470 Sephacryl S-400 HR column equilibrated with gel filtration buffer containing 20 mM

471 Tris-HCl (pH 7.5), 200 mM NaCl and 1 mM $MgCl_2$ at a flow rate of 0.5 mL/min at 4°C.

472 Thyroglobulin (669 kDa; Gel Filtration Calibration Kits; Cytiva) was dissolved in gel

473 filtration buffer and loaded onto the column as a size standard at a flow rate of 0.5

474 mL/min. The stoichiometry of protein complexes was estimated by densitometry of

475 SDS-PAGE gels stained with CBB, using a scanner (GT-9800F; Epson, Nagano,

476 Japan) and ImageJ (9).

477 **BN-PAGE and in-gel ATPase activity assays** BN-PAGE was performed

478 according to the user manual of the Native PAGE Novex Bis-Tris Gel System

23

479   (Thermo Fisher Scientific, Waltham, MA). For BN-PAGE of the F_1-like ATPase unit,

480   the isolated chain particle (motor) fraction was mixed with sodium cholate (1.5%)

481   and incubated at 4°C for 9 h. When this sample was mixed with a sample buffer,

482   NativePAGE™ 5% (w/v) G-250 sample additive was also added at 0.5% (w/v) to

483   prevent protein aggregation. Thyroglobulin was dissolved in water and used as a

484   negative control for the In-gel ATPase activity assay. For the In-gel ATPase activity

485   assay (61, 62), native gels were incubated with gentle shaking overnight at 24–

486   27°C in activity buffer containing 270 mM glycine, 35 mM Tris (pH 8.4), 4 mM ATP,

487   14 mM $MgSO_4$, and 0.2% (w/v) $Pb(NO_3)_2$. The gels were rinsed once with water and

488   images were taken using ImageQuant LAS 4000 mini (Cytiva). White precipitates

489   were then dissolved by gentle shaking overnight at 24–27°C with 50% (v/v)

490   methanol and 10% (v/v) acetic acid in water. The gels were restained with 0.025%

491   (w/v) CBB G-250 and 10% acetic acid in water for 80 min at 24–27°C with gentle

492   shaking and destained with 10% (v/v) ethanol and 10% acetic acid in water for 180

493   min at 24–27°C with gentle shaking. The gels were rinsed once with water and

494   images were taken using ImageQuant LAS 4000 mini.

495   **Phosphate-release assay** The isolated chain particle solution was dialyzed

496   overnight using 20 mM Tris-HCl (pH 7.5), 150 mM NaCl, and 2 mM $MgCl_2$. ATPase

497   activity was assayed by a continuous spectrophotometric method using a

498   2-amino-6-mercapto-7-methylpurine ribonucleoside–purine nucleoside

499   phosphorylase reaction to detect released inorganic phosphate (EnzChek kit;

500   Thermo Fisher Scientific) (63). The reaction mixture was as follows: 15.7 nM motor,

24

501   20 mM Tris-HCl (pH 7.5), 150 mM NaCl, 2 mM $MgCl_2$ and 0.01–1 mM ATP in a total

502   volume of 0.2 mL at 25°C. Sodium azide was added to 15.4 mM final concentration

503   when the reaction was started. The protein amount of the MMOB1670 comprising

504   F_1-ATPase β-subunit paralogs was estimated using densitometric of SDS-PAGE.

505   **Negative-staining EM and image processing.** The isolated chain particle

506   solution was placed on a glow-discharged (PIB-10; VACUUM DEVICE, Ibaraki,

507   Japan) carbon-coated grid (F-400; Nisshin EM Co., Tokyo, Japan) and incubated for

508   1 min at 24–27°C. The solution was then removed, and the grid was stained with

509   2% uranyl acetate (w/v) for 30 s. The stain was then removed, and the grid was

510   air-dried. To observe the F_1-like ATPase unit and the chain, the grids were washed

511   with water after 1 min of incubation and then treated as described for the isolated

512   chain particle solution. Samples were observed using a transmission EM (JEM1010,

513   JEOL) at 80 kV, equipped with a FastScan-F214 (T) charge-coupled-device (CCD)

514   camera (TVIPS, Gauting, Germany), and images were captured at 2.58 Å/pix.

515   The contrast transfer function parameters for electron micrographs were

516   estimated using Gctf (64). Further image processing was performed using RELION

517   3.0 (34). A total of 2148 particles for the chain particle and 11687 particles for the

518   F_1-like ATPase unit were automatically selected with box sizes of 180 × 180 and

519   100 × 100 pixels, respectively. These particle images were binned to 5.16 Å/pix. For

520   the chain particle, the particle images were 2D-classified into 100 classes. For the

521   F_1-like ATPase unit, particle images were 2D-classified in four rounds, and the

522   selected 7381 particles were re-extracted with the pixel size returned to the

25

523   unbinned image and then 2D-classified into 50 classes.

524   For reconstruction of the 3D chain structure, 2127 particles were manually

525   selected for chains with a box size of 276 × 276 pixels with ~50% overlap. These

526   particle images were binned to 5.16 Å/pix. Particle images were 2D-classified in two

527   rounds, and the selected 1709 particles were used to reconstruct the initial model

528   with a final resolution limit of 50 Å. The initial model and selected particles were

529   used to perform 3D refinement. Reprojection images were produced from the 3D

530   map using the relion_project command in RELION. The 3D map was visualized

531   using UCSF Chimera 1.14 (65). Atomic models of F_1-ATPase catalytic $(\alpha\beta)_3$ from *B.*

532   *subtilis* (PDB ID 6N2Y) were fitted into the 3D map using command of "Fit in map" in

533   UCSF Chimera.

534   **HS-AFM.** Imaging was performed with a laboratory-built tapping mode HS-AFM

535   (66, 67), using small cantilevers (BLAC10DS-A2, Olympus; resonant frequency,

536   ~0.5 MHz in water; quality factor, ~1.5 in water; spring constant, ~0.1 N/m). The

537   cantilever's free-oscillation peak-to-peak amplitude (A_0) and set-point amplitude

538   were set at ~2.5 nm and ~0.8 × A_0, respectively. The probe tip was grown on the

539   original tip end of a cantilever through electron beam deposition and further

540   sharpened using a radio frequency plasma etcher (PE-2000, South Bay Technology,

541   Redondo Beach, CA) under an argon gas atmosphere (typically at 180 mTorr and

542   15 W for 3 min). The sample was deposited on a freshly cleaved mica disc glued to

543   a glass stage beforehand. After 3.5 min, the stage surface was immersed in a liquid

544   cell containing an observation buffer [20 mM Tris-HCl (pH 7.5), 50 mM KCl, 2 mM

26

545    $MgCl_2$]. Imaging was performed at 24–27°C. AFM images were processed using a

546   low-pass filter to remove spike noise and make the *xy*-plane flat and analyzed using

547   Kodec software (version 4.4.7.39) (68). Surface profiles and smoothing were

548   performed using ImageJ software.

570   **Figure Legends**

571   **FIG 1. Gliding machinery of *Mycoplasma mobile*.** (A) Optical microscopy of cells

572   (upper) and trajectories of gliding cells (lower). The gliding direction is indicated by a

573   black arrow. The 4-second trajectory is colored from red to blue. (B) Schematic

574   illustration of gliding machinery based on the present study. In the whole cell shown

575   in upper illustration, the internal structure and legs are colored gray and red,

576   respectively. The actual cell has about 28 chains, each consisting of 17 particles,

577   although a more limited number is illustrated here. A single unit of the surface

578   structure and a chain of the internal structure are magnified in the lower illustration.

579   "Motor" is identical to "chain particle." (C) ORFs for the internal structure. The

580   components of the internal structure are colored gray. Type 2 ATPase operon is at

581   the top. Motor components revealed in the present study are marked by colored

582   boxes, corresponding to the colored components of the lower illustration in panel B.

583

584   **FIG 2. Isolation profile and characterization of chain particle.** (A) Protein profile

585   of each fraction. The fractions were subjected to SDS-12.5% PAGE gel and stained

586   with CBB. Lane 1, lysate of *M. mobile* cells; lane 2, Triton-soluble fraction; lane 3,

587   Triton-insoluble fraction; lane 4, supernatant after incubation in a buffer containing

28

588   137 mM NaCl; lane 5, peak fraction of Superdex 200 gel filtration chromatography.

589   The bands of the chain particle components are marked by black triangles.

590   Molecular masses are shown on the left. (B) Gel filtration assay using Sephacryl

591   S-400 HR column. The peak position of thyroglobulin (669 kDa) is marked by a

592   purple triangle. The peak fraction of the chain particles marked by an orange

593   triangle was analyzed by SDS-12.5% PAGE. The bands of the chain particle

594   components are marked by black triangles. (C) BN-PAGE (left) and In-gel ATPase

595   activity assay (right). Isolated chain particle and thyroglobulin, which has no ATPase

596   activity, were subjected to 3 to 12% gradient BN-PAGE. The band positions of the

597   chain particle and thyroglobulin are marked by black and open triangles,

598   respectively. White precipitates, indicating ATPase activity, appeared only at the

599   band position of the chain particle. Molecular masses are shown on the left. (D)

600   Phosphate release assay under various ATP concentrations with and without

601   sodium azide. The ATPase activities under 0- and 15.4-mM sodium azide are

602   marked by red and green filled circles, respectively (n = 3). These data were fitted

603   by the Michaelis-Menten equation as solid lines.

604

605   **FIG 3. Negative-staining EM and HS-AFM of chain particle (motor).** (A) Electron

606   micrograph of negatively stained chain particles. (B) Images of individual particles.

607   (C) Representative 2D averaged image. A mirror image is shown to match the

608   orientation of the hexameric ring observed by HS-AFM. (D) Illustration based on the

609   averaged image in panel C. Filamentous structures are marked by asterisks at an

610   end. The double-headed arrow shows the distance between the centers of the

611   hexamers. (E) Two patterns of HS-AFM images. The motor (chain particle) was

612   scanned at 56 × 56 pixels in an area of 70 × 70 nm^2 with a scanning rate of 100 ms

613   per frame. Illustrations for patterns I and II (left side) were depicted based on 3D

614   chain model shown in Fig. 5. Observation directions are indicated by arrows.

615   Protrusions are marked by blue triangles. Images of patterns I and II are shown in

616   green and purple frames, respectively. (F) Averaged images for patterns I (green

617   frame) and II (purple frame). The motor was scanned at 50 × 50 pixels in an area of

618   40 × 40 nm^2 with a scanning rate of 100 ms per frame. The images were produced

619   by averaging three successive video frames. (G) HS-AFM slice image showing two

620   hexameric rings (upper) and averaged EM image (lower). Upper: The red broken

621   boxed area in panel F was sliced for the height 9.8–11.3 nm from the substrate

622   surface, processed for smoothing, and magnified. The angle alignments of two

623   hexamers are schematically shown in the left upper. Lower: The central part of

624   panel C was excised and aligned to compare with the upper panel. Subunits of the

625   hexamer are marked by red circles. (H) Surface profiles along the lines in pattern I

626   (green) and II (purple). The upper and lower images in panel F were each profiled at

627   the green and purple lines passing the globule centers. The dimples and the peaks

628   are marked by open and black triangles, respectively. (I) Shedding process of the

629   peaks of pattern II particle shown in panel E. The peaks are marked by red triangles.

630   (J) Surface profile showing the disappeared peaks. The images in panel I were

631   each profiled at the clear blue, brown, and gray lines passing the globule centers.

632 The peaks are marked by black triangles. The double-headed arrows show the

633 peak heights. (K) HS-AFM image of the motor with seven lateral protrusions. The

634 motor was scanned at 120 × 120 pixels in an area of 120 × 120 nm^2 with a scanning

635 rate of 500 ms per frame. Lateral protrusions are indicated by blue triangles. (L)

636 Fluctuations of the protrusions of the particle shown in panel K. The images were

637 sliced for the height 0–7.0 nm from the substrate surface. The moving directions are

638 indicated by arrows. In all HS-AFM images, the color bar on the right shows the

639 range of image heights.

640

641 **FIG 4. Isolation of F$_1$-like ATPase unit.** (A) BN-PAGE of motors (chain particles)

642 treated with 1.5% sodium cholate (left) and In-gel ATPase activity assay (right).

643 Motors, motors treated with 1.5% sodium cholate (SC treatment), and thyroglobulin

644 were subjected to 3 to 12% gradient BN-PAGE. The band of the motor is marked by

645 a black triangle. The band of the ATPase unit revealed by sodium cholate treatment

646 is indicated by an open triangle. The white lead phosphate bands indicate ATPase

647 activity. Molecular masses are shown on the left. (B) Gel filtration assay using a

648 Sephacryl S-400 HR column. The light blue lines show a Gaussian fit. (C) The F1–

649 F13 fractions in the gel filtration assay indicated by the green line in panel B were

650 subjected to SDS-12.5% PAGE and stained with CBB. Bands for motor components

651 are marked by black triangles. (D) Comparison of band patterns between F6 and

652 the motor on CBB-stained SDS-12.5% PAGE. The position of F6 in the elution

653 volume is marked by a green triangle in panel B. (E) Electron micrograph of

31

654   negatively stained ATPase in F6. (F) Images of individual particles. (G)

655   Representative 2D averaged images (upper) and depictions of their structures

656   (lower). Upper: Hook structures in the hexameric ring and the stalks are marked by

657   green and orange triangles, respectively. Lower: The hexameric part, hook

658   structures and the stalk are colored rose, green and orange, respectively.

659

660   **FIG 5. Motor chain structure.** (A) Protein profile of chain fraction. CBB-stained

661   SDS-12.5% PAGE image of the crude chain fraction. The bands of motor

662   components, MMOBs 1670, 4530, 1660, 1630, and 1620 are marked by black

663   triangles from upper to lower. (B) Electron micrograph of negatively stained chains.

664   The chain structures are marked by blue lines. (C) Magnified chain images. (D)

665   Representative 2D averaged images. (E) Three-dimensional reconstruction of chain

666   containing two F_1-like ATPase dimers. The 3D map is visualized at a density

667   threshold (contour level = 0.026). The central stalks are marked by open triangles.

668   (F) Superposition of the atomic model of *Bacillus* F_1-ATPase catalytic $(\alpha\beta)_3$ (PDB ID

669   6N2Y) (37) onto the 3D chain structure. The α and β subunits are colored salmon

670   and turquoise, respectively. The central stalk and protrusions from hexameric rings

671   are marked by open and black triangles, respectively. (G) Cross section of

672   mushroom-like structures. Central stalks are marked by broken circles. The

673   double-headed arrow shows the length of the protrusion. Corresponding

674   mushroom-like structures are marked (a)–(d) in panel F. (H) Comparison between

675   the motor image from Fig. 3C (left) and the chain reprojection (middle). The

676   reprojected image is viewed from the angle used for the right image of panel E.

677   Short filaments corresponding to the position of the connecting bulge are marked by

678   asterisks. A depiction of the chain model based on the comparison (right). (I)

679   Comparison between the averaged chain image from ECT (left) and the chain

680   reprojection (middle). Left image was modified from (23). The chain was reprojected

681   from an angle close to the middle image in panel E. Inner sides and membrane

682   relative to the chain are marked by i and m, respectively. The protrusion from the

683   globule corresponding to the central stalk from the hexameric ring, one from the

684   connecting bulge and the globule attached to the connecting bulge are marked by

685   orange, light blue and green triangles, respectively. The areas of image densities

686   that were visualized only in the ECT image are marked by broken lines. An

687   illustration depicts a chain model based on the comparison (right).

688

689   **FIG 6. Working models for force transmission mechanism.** The gliding direction

690   is indicated by a red arrow. The regions marked in gray were visualized only in the

691   ECT image. The crank protein Gli521 and the leg protein Gli349 are colored green

692   and red, respectively. (i) Contraction model: The force generated by the hexameric

693   ring displaces the motor along the gliding direction. The displacements are

694   transmitted through the membrane to Gli521. (ii) Rotation model: The force

695   generated by the hexameric ring rotates the central stalk in a mechanism similar to

696   that of F_1-ATPase. The rotational motion is transmitted across the membrane to

697   Gli521.The generation and transmission of forces are presented by black arrows for

33

698 both models.

699

700 **FIG S1 Conditions to solubilize chain particle.** The Triton-insoluble fraction was

701 treated with buffers containing the specified concentrations of NaCl and centrifuged.

702 The Triton-insoluble fraction (TI), the supernatants (S) and the pellets (P) were

703 analyzed by SDS-12.5% PAGE. MMOB1670, a component of the chain, is marked

704 by a black triangle. Molecular masses are shown on the left.

705

706 **FIG S2 Two-dimensional averaged images of chain particle obtained by**

707 **negative-staining EM.** Four classes of clear particle images from 20 classes are

708 represented. As mentioned in Fig. 3C, they were mirrored.

709

710 **FIG S3 Protein profiles of gel-filtration fractions visualized by reverse-staining**

711 **method.** Motor components are marked by black triangles on the right. Molecular

712 masses are shown on the left. Fractions F10–F13 correspond to the first half of the

713 large three peaks in the elution volume from 80–100 mL shown in Fig. 4B.

714

715 **FIG S4 Two-dimensional averaged images of globular complex in F6.** Fifteen

716 classes of clear particle images from 50 classes are represented.

717

718 **FIG S5 Reprojection images of chain.** Two-dimensional averaged images (upper)

719 and the corresponding reprojection images (lower) calculated from the 3D map of

720   the chain are compared.

721

722   **Movie S1 HS-AFM movie showing pattern I particles** The particles were scanned

723   at 10 fps. The scanning field was 70 × 70 nm^2 with 56 × 56 pixels. The video was

724   played at 10 fps.

725

726   **Movie S2 HS-AFM movie showing pattern II particles** The particles were

727   scanned at 10 fps. The scanning field was 70 × 70 nm^2 with 56 × 56 pixels. The

728   video was played at 10 fps.

729

730   **Movie S3 HS-AFM movie showing the shedding process of the peaks.** The

731   particles were scanned at 10 fps. The scanning field was 70 × 70 nm^2 with 56 × 56

732   pixels. The video was played at 10 fps. The peaks are indicated by the red triangles.

733

734   **Movie S4 HS-AFM movie showing fluctuations in protrusions.** The particles

735   were scanned at 2 fps. The scanning field was 120 × 120 nm^2 with 120 × 120 pixels.

736   The video was played at 1 fps. The protrusions are indicated by the red triangles.

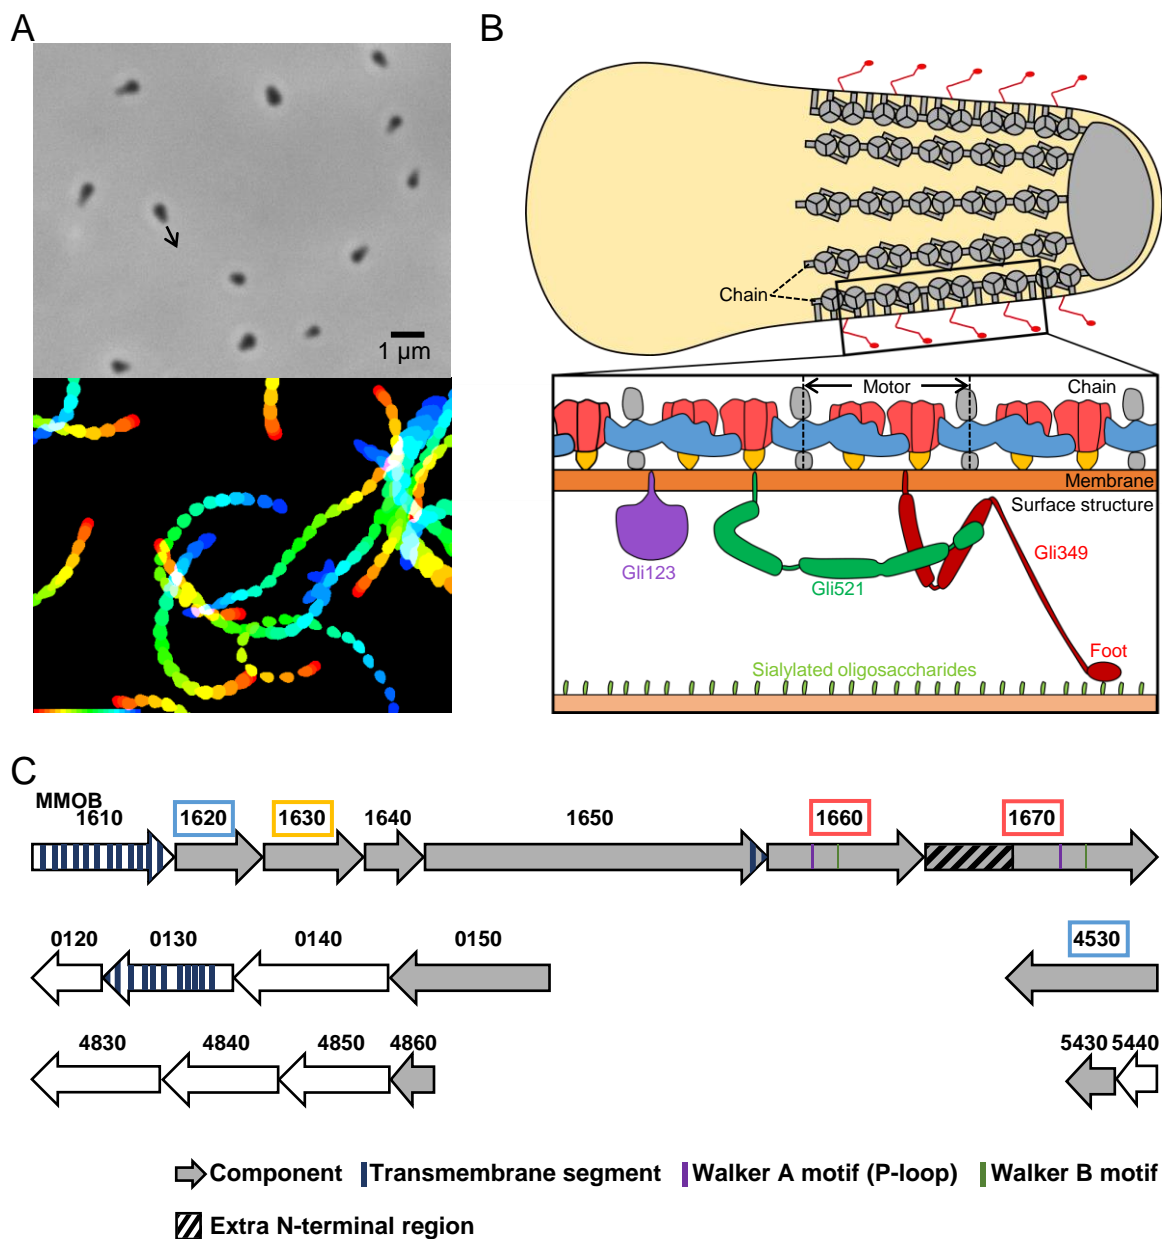

FIG 1. Gliding machinery of *Mycoplasma mobile*. (A) Optical microscopy of cells (upper) and trajectories of gliding cells (lower). The gliding direction is indicated by a black arrow. The 4-second trajectory is colored from red to blue. (B) Schematic illustration of gliding machinery based on the present study. In the whole cell shown in upper illustration, the internal structure and legs are colored gray and red, respectively. The actual cell has about 28 chains, each consisting of 17 particles, although a more limited number is illustrated here. A single unit of the surface structure and a chain of the internal structure are magnified in the lower illustration. "Motor" is identical to "chain particle." (C) ORFs for the internal structure. The components of the internal structure are colored gray. Type 2 ATPase operon is at the top. Motor components revealed in the present study are marked by colored boxes, corresponding to the colored components of the lower illustration in panel B.

Figure 2
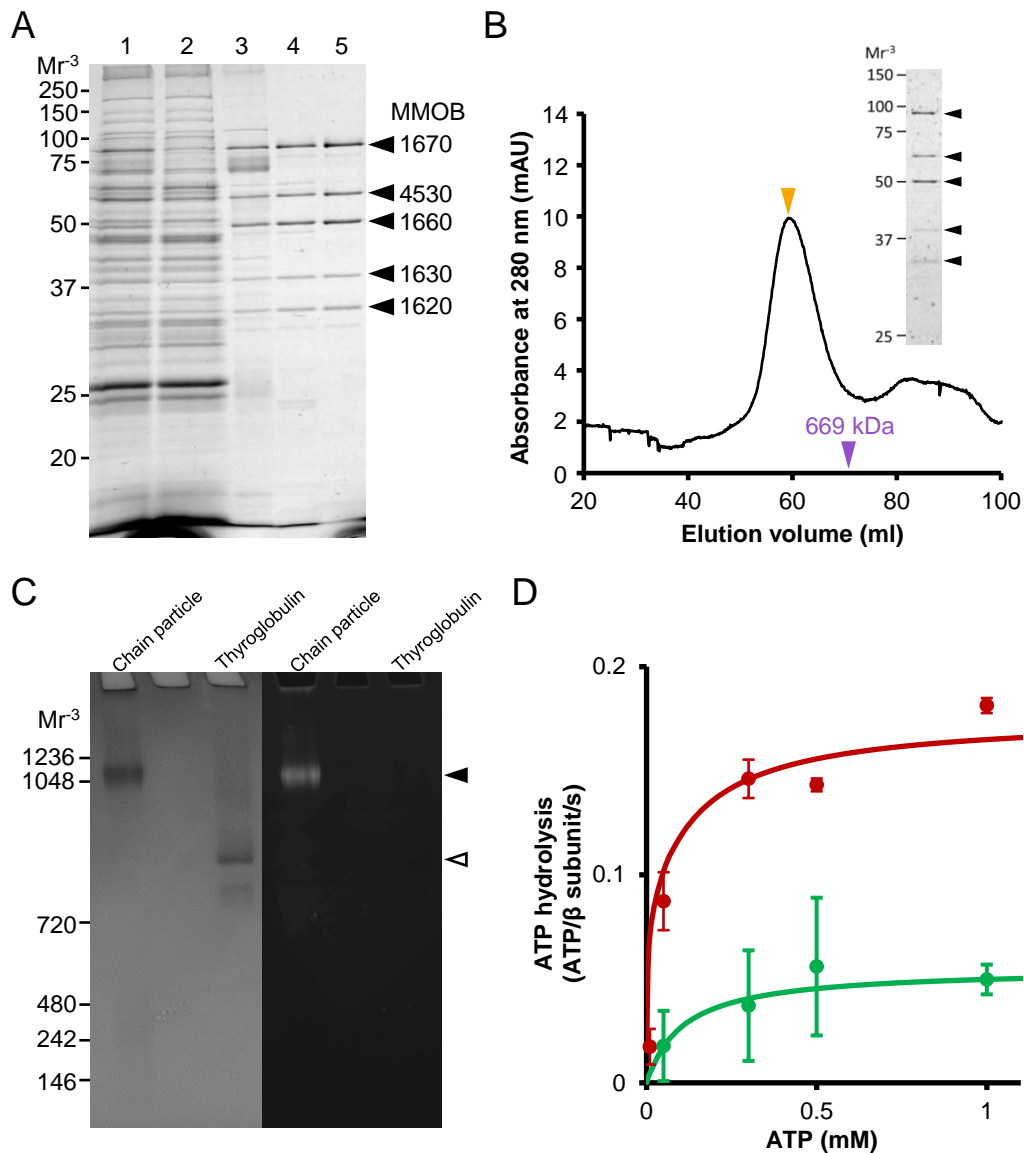

FIG 2. Isolation profile and characterization of chain particle. (A) Protein profile of each fraction. The fractions were subjected to SDS-12.5% PAGE gel and stained with CBB. Lane 1, lysate of *M. mobile* cells; lane 2, Triton-soluble fraction; lane 3, Triton-insoluble fraction; lane 4, supernatant after incubation in a buffer containing 137 mM NaCl; lane 5, peak fraction of Superdex 200 gel filtration chromatography. The bands of the chain particle components are marked by black triangles. Molecular masses are shown on the left. (B) Gel filtration assay using Sephacryl S-400 HR column. The peak position of thyroglobulin (669 kDa) is marked by a purple triangle. The peak fraction of the chain particles marked by an orange triangle was analyzed by SDS-12.5% PAGE. The bands of the chain particle components are marked by black triangles. (C) BN-PAGE (left) and In-gel ATPase activity assay (right). Isolated chain particle and thyroglobulin, which has no ATPase activity, were subjected to 3 to 12% gradient BN-PAGE. The band positions of the chain particle and thyroglobulin are marked by black and open triangles, respectively. White precipitates, indicating ATPase activity, appeared only at the band position of the chain particle. Molecular masses are shown on the left. (D) Phosphate release assay under various ATP concentrations with and without sodium azide. The ATPase activities under 0- and 15.4-mM sodium azide are marked by red and green filled circles, respectively (n = 3). These data were fitted by the Michaelis-Menten equation as solid lines.

Figure 3
FIG 3. Negative-staining EM and HS-AFM of chain particle (motor). (A) Electron micrograph of negatively stained chain particles. (B) Images of individual particles. (C) Representative 2D averaged image. A mirror image is shown to match the orientation of the hexameric ring observed by HS-AFM. (D) Illustration based on the averaged image in panel C. Filamentous structures are marked by asterisks at an end. The double-headed arrow shows the distance between the centers of the hexamers. (E) Two patterns of HS-AFM images. The motor (chain particle) was scanned at 56×56 pixels in an area of 70×70 nm^2 with a scanning rate of 100 ms per frame. Illustrations for patterns I and II (left side) were depicted based on 3D chain model shown in Fig. 5. Observation directions are indicated by arrows. Protrusions are marked by blue triangles. Images of patterns I and II are shown in green and purple frames, respectively. (F) Averaged images for patterns I (green frame) and II (purple frame). The motor was scanned at 50×50 pixels in an area of 40×40 nm^2 with a scanning rate of 100 ms per frame. The images were produced by averaging three successive video frames. (G) HS-AFM slice image showing two hexameric rings (upper) and averaged EM image (lower). Upper: The red broken boxed area in panel F was sliced for the height 9.8–11.3 nm from the substrate surface, processed for smoothing, and magnified. The angle alignments of two hexamers are schematically shown in the left upper. Lower: The central part of panel C was excised and aligned to compare with the upper panel. Subunits of the hexamer are marked by red circles. (H) Surface profiles along the lines in pattern I (green) and II (purple). The upper and lower images in panel F were each profiled at the green and purple lines passing the globule centers. The dimples and the peaks are marked by open and black triangles, respectively. (I) Shedding process of the peaks of pattern II particle shown in panel E. The peaks are marked by red triangles. (J) Surface profile showing the disappeared peaks. The images in panel I were each profiled at the clear blue, brown, and gray lines passing the globule centers. The peaks are marked by black triangles. The double-headed arrows show the peak heights. (K) HS-AFM image of the motor with seven lateral protrusions. The motor was scanned at 120×120 pixels in an area of 120×120 nm^2 with a scanning rate of 500 ms per frame. Lateral protrusions are indicated by blue triangles. (L) Fluctuations of the protrusions of the particle shown in panel K. The images were sliced for the height 0–7.0 nm from the substrate surface. The moving directions are indicated by arrows. In all HS-AFM images, the color bar on the right shows the range of image heights.
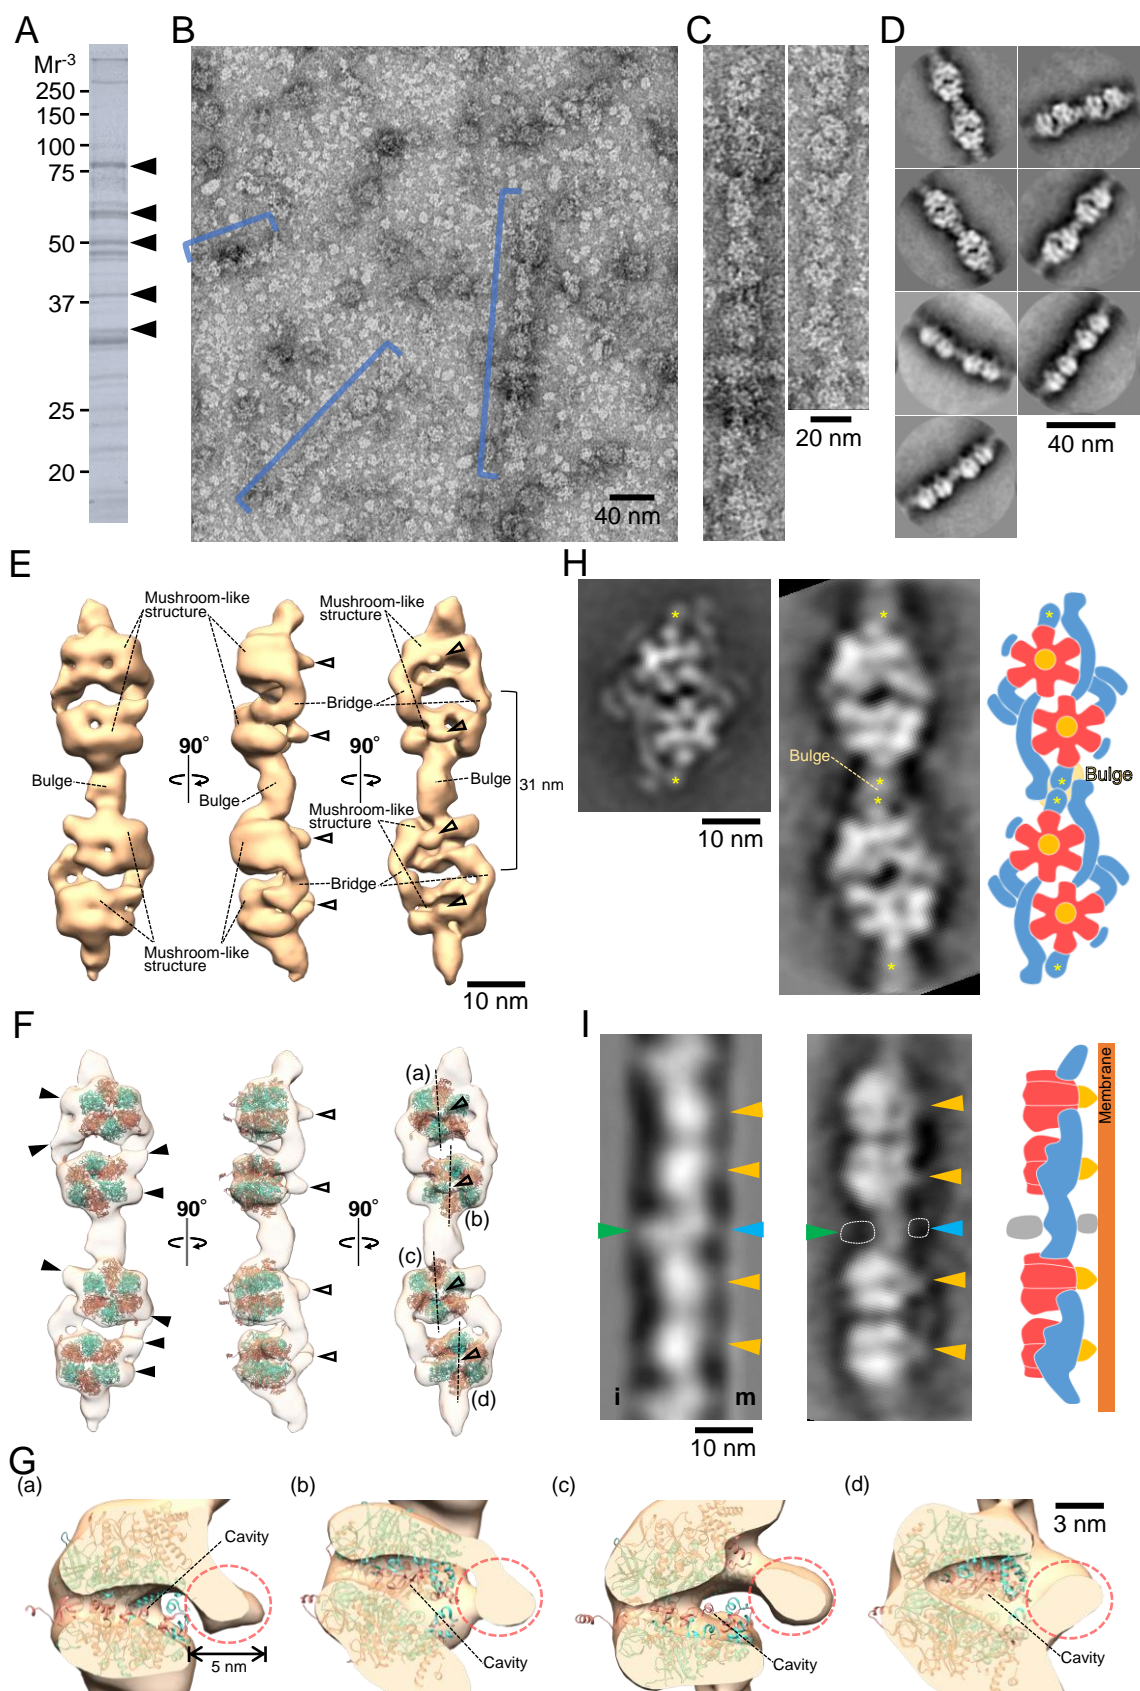

Figure 4
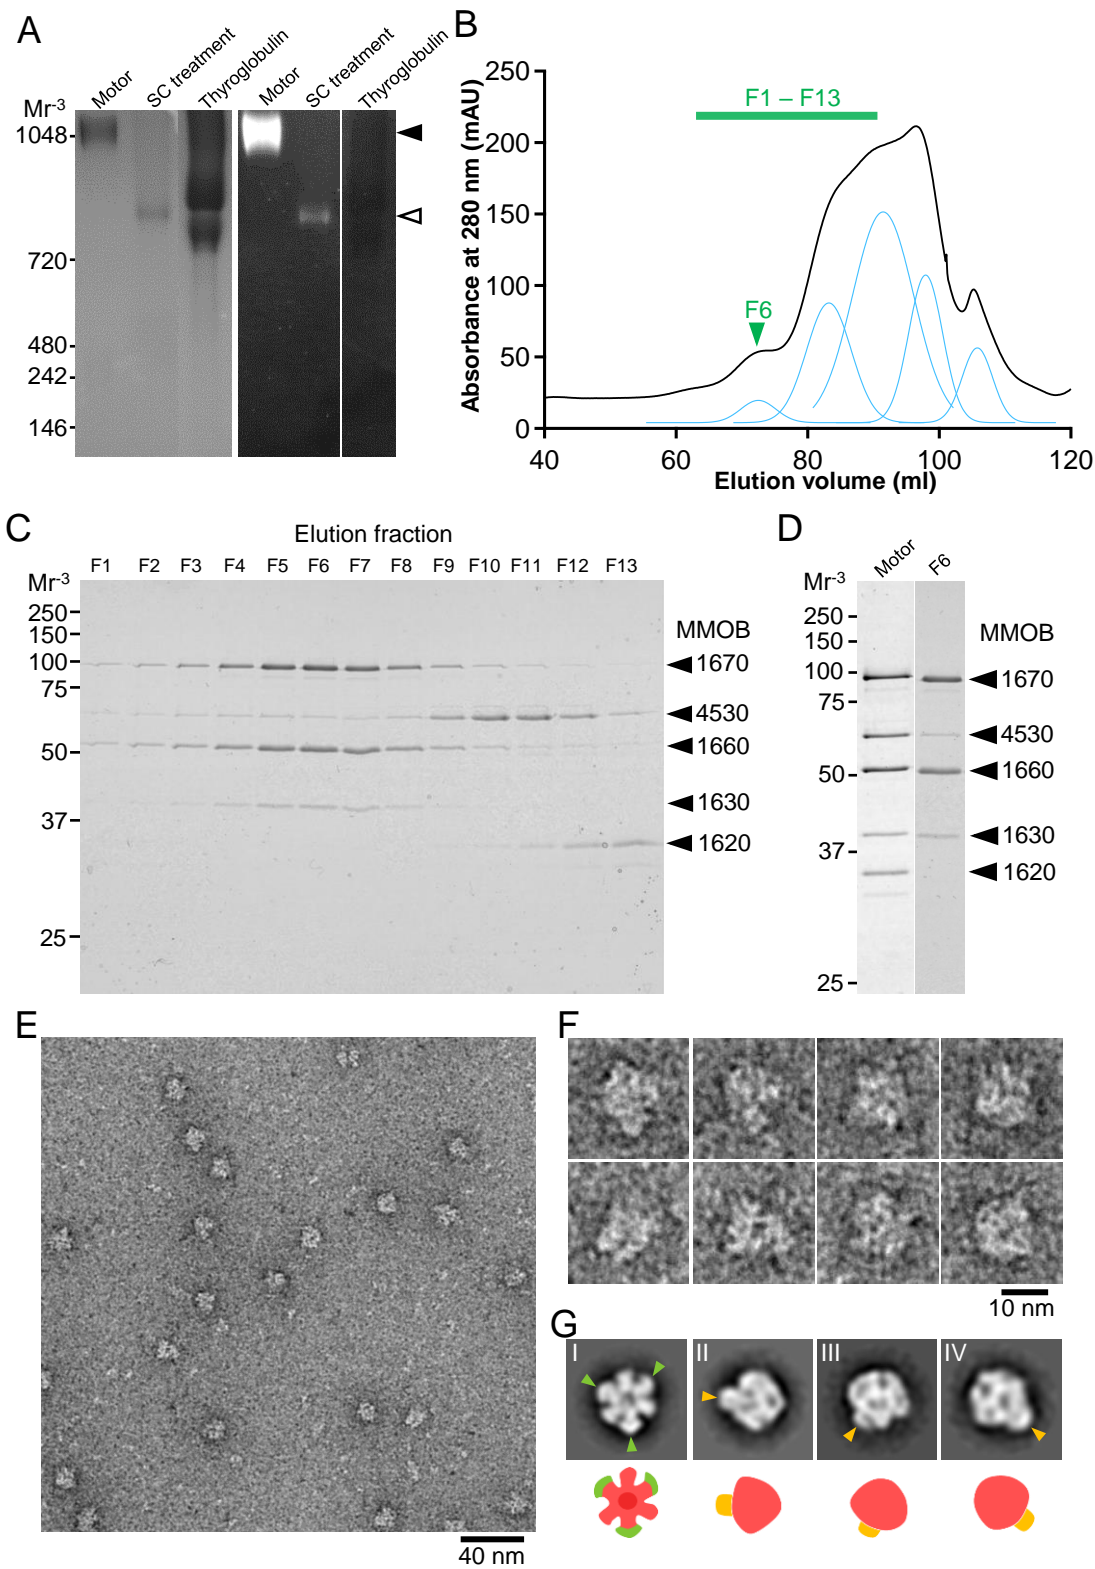

FIG 4. Isolation of F$_1$-like ATPase unit. (A) BN-PAGE of motors (chain particles) treated with 1.5% sodium cholate (left) and In-gel ATPase activity assay (right). Motors, motors treated with 1.5% sodium cholate (SC treatment), and thyroglobulin were subjected to 3 to 12% gradient BN-PAGE. The band of the motor is marked by a black triangle. The band of the ATPase unit revealed by sodium cholate treatment is indicated by an open triangle. The white lead phosphate bands indicate ATPase activity. Molecular masses are shown on the left. (B) Gel filtration assay using a Sephacryl S-400 HR column. The light blue lines show a Gaussian fit. (C) The F1–F13 fractions in the gel filtration assay indicated by the green line in panel B were subjected to SDS-12.5% PAGE and stained with CBB. Bands for motor components are marked by black triangles. (D) Comparison of band patterns between F6 and the motor on CBB-stained SDS-12.5% PAGE. The position of F6 in the elution volume is marked by a green triangle in panel B. (E) Electron micrograph of negatively stained ATPase in F6. (F) Images of individual particles. (G) Representative 2D averaged images (upper) and depictions of their structures (lower). Upper: Hook structures in the hexameric ring and the stalks are marked by green and orange triangles, respectively. Lower: The hexameric part, hook structures and the stalk are colored rose, green and orange, respectively.

FIG 5. Motor chain structure. (A) Protein profile of chain fraction. CBB-stained SDS-12.5% PAGE image of the crude chain fraction. The bands of motor components, MMOBs 1670, 4530, 1660, 1630, and 1620 are marked by black triangles from upper to lower. (B) Electron micrograph of negatively stained chains. The chain structures are marked by blue lines. (C) Magnified chain images. (D) Representative 2D averaged images. (E) Three-dimensional reconstruction of chain containing two F_1-like ATPase dimers. The 3D map is visualized at a density threshold (contour level = 0.026). The central stalks are marked by open triangles. (F) Superposition of the atomic model of *Bacillus* F_1-ATPase catalytic $(\alpha\beta)_3$ (PDB ID 6N2Y) (37) onto the 3D chain structure. The α and β subunits are colored salmon and turquoise, respectively. The central stalk and protrusions from hexameric rings are marked by open and black triangles, respectively. (G) Cross section of mushroom-like structures. Central stalks are marked by broken circles. The double-headed arrow shows the length of the protrusion. Corresponding mushroom-like structures are marked (a)–(d) in panel F. (H) Comparison between the motor image from Fig. 3C (left) and the chain reprojection (middle). The reprojected image is viewed from the angle used for the right image of panel E. Short filaments corresponding to the position of the connecting bulge are marked by asterisks. A depiction of the chain model based on the comparison (right). (I) Comparison between the averaged chain image from ECT (left) and the chain reprojection (middle). Left image was modified from (23). The chain was reprojected from an angle close to the middle image in panel E. Inner sides and membrane relative to the chain are marked by i and m, respectively. The protrusion from the globule corresponding to the central stalk from the hexameric ring, one from the connecting bulge and the globule attached to the connecting bulge are marked by orange, light blue and green triangles, respectively. The areas of image densities that were visualized only in the ECT image are marked by broken lines. An illustration depicts a chain model based on the comparison (right).
Figure 6
FIG 6. Working models for force transmission mechanism. The gliding direction is indicated by a red arrow. The regions marked in gray were visualized only in the ECT image. The crank protein Gli521 and the leg protein Gli349 are colored green and red, respectively. (i) Contraction model: The force generated by the hexameric ring displaces the motor along the gliding direction. The displacements are transmitted through the membrane to Gli521. (ii) Rotation model: The force generated by the hexameric ring rotates the central stalk in a mechanism similar to that of F_1-ATPase. The rotational motion is transmitted across the membrane to Gli521.The generation and transmission of forces are presented by black arrows for both models.

Supplementary figure 1
FIG S1 Conditions to solubilize chain particle. The Triton-insoluble fraction was treated with buffers containing the specified concentrations of NaCl and centrifuged. The Triton-insoluble fraction (TI), the supernatants (S) and the pellets (P) were analyzed by SDS-12.5% PAGE. MMOB1670, a component of the chain, is marked by a black triangle. Molecular masses are shown on the left.

FIG S5 Reprojection images of chain. Two-dimensional averaged images (upper) and the corresponding reprojection images (lower) calculated from the 3D map of the chain are compared.
Movie S1
**Movie S1 HS-AFM movie showing pattern I particles** The particles were scanned at 10 fps. The scanning field was 70 × 70 nm^2 with 56 × 56 pixels. The video was played at 10 fps.

Movie S2

Movie S2 HS-AFM movie showing pattern II particles The particles were scanned at 10 fps. The scanning field was 70 × 70 nm^2 with 56 × 56 pixels. The video was played at 10 fps.

Movie S3

Movie S3 HS-AFM movie showing the shedding process of the peaks.
The particles were scanned at 10 fps. The scanning field was 70 × 70 nm^2 with 56 × 56 pixels. The video was played at 10 fps. The peaks are indicated by the red triangles.

Movie S4
Movie S4 HS-AFM movie showing fluctuations in protrusions. The particles were scanned at 2 fps. The scanning field was 120 × 120 nm^2 with 120 × 120 pixels. The video was played at 1 fps. The protrusions are indicated by the red triangles.
