Summary

Mechanisms of tissue-specific gene expression regulation via spatial coordination of gene promoters and distal regulatory elements are still poorly understood. We investigated the 3D genome organization of developing murine T cells and identified SATB1, a tissue-specific genome organizer, enriched at the anchors of promoter-enhancer chromatin loops. We assessed the function of SATB1 in T cell chromatin organization and compared it to the conventional genome organizer CTCF. SATB1 builds a more refined layer of genome organization upon a CTCF scaffold. To understand the regulatory implications of SATB1 loopscape structure, we generated $Satb1^{fl/fl}Cd4$-Cre^{+} ($Satb1$ cKO) conditional knockout animals which suffered from autoimmunity. We aimed to identify molecular mechanisms responsible for the deregulation of the immune system in $Satb1$ cKO animals. H3K27ac HiChIP and Hi-C experiments indicated that SATB1 primarily mediates promoter-enhancer loops affecting master regulator genes (such as $Bcl6$), the T cell receptor locus and adhesion molecule genes, collectively being critical for cell lineage specification and immune system homeostasis. Our findings unravel the function of a tissue-specific factor that controls transcription programs, via spatial chromatin arrangements complementary to the chromatin structure imposed by ubiquitously expressed genome organizers.

Keywords: SATB1, CTCF, enhancers, T cells, thymocytes, nuclear matrix, chromatin organization, adaptive immunity, Hi-C, HiChIP, $Bcl6$, TCR.

Introduction

In order to store the large amount of genetic information, higher eukaryotes developed spatial and functional genome organization into compartments and domains. The A and B compartments represent the largest organizational units and they functionally correspond to active and inactive chromatin regions, respectively (Lieberman-Aiden et al., 2009; Rao et al., 2014). These compartments are further partitioned into topologically associated domains (TADs; Dixon et al., 2012; Nora et al., 2012), although due to their heterogeneous nature, new terminology better reflecting the reality is slowly being adopted (Rowley and Corces, 2018). Structural segmentation of chromatin in mammals is driven by architectural proteins such as CTCF and the cohesin complex (Nora et al., 2017; Rao et al., 2017; Schwarzer et al., 2017). Depletion of either CTCF (Nora et al., 2017), cohesin (Rao et al., 2017) or its loading factor *Nipbl* (Schwarzer et al., 2017) leads to global disruption of TAD organization, yet surprisingly with only modest transcriptional changes and unaffected A/B compartments. This, together with the recent findings at base-pair resolution (Hua et al., 2021), indicates the presence of additional mechanisms of the three-dimensional (3D) chromatin organization. The elimination of cohesin loading factor *Nipbl* unveiled a finer compartment structure that reflected the underlying epigenetic landscape (Schwarzer et al., 2017). This observation is in line with the model in which the primary driver of chromatin organization is the actual transcriptional state (Rowley et al., 2017). Indeed, RNA polymerase II and transcription itself are tightly linked to the formation of finer-scale structures of chromatin organization (Hsieh et al., 2020). Nonetheless, transcriptional inhibition has only a modest effect on promoter-enhancer contacts (Hsieh et al., 2020). Similarly, the inhibition of BET proteins, degradation of BRD4 or dissolution of transcriptional phase condensates all yield in the disrupted transcription, however they also have just a little impact on promoter-enhancer interactions (Crump et al., 2021). In contrast, an experimental disruption of TADs (Lupiáñez et al., 2015) or direct manipulation of promoter-enhancer contacts (Deng et al., 2012) both result in alterations of gene expression. Additionally, chromatin reorganization often precedes changes in transcription during development and differentiation (Apostolou et al., 2013;

4

74 Stadhouders et al., 2018), suggesting that in many scenarios 3D genome organization instructs the

75 transcriptional programs. However, the precise mechanisms on how chromatin organization is linked to

76 gene expression regulation, especially in the context of cell lineage specification, still remain poorly

77 understood. Several transcription factors have been shown to mediate promoter-enhancer interactions

78 and thus also the underlying transcriptional programs in a tissue-specific manner and often even

79 independent of CTCF and cohesin (Giammartino et al., 2020; Kim and Shendure, 2019; Stadhouders et

80 al., 2019). Such an additional regulatory layer of chromatin organization, provided by transcription

81 factors, may represent the missing link between high order chromatin structure and transcriptional

82 regulation.

83   In this work, we aimed to identify drivers of regulatory chromatin loops in developing murine T

84 cells, as a great model of tissue-specific gene expression regulation. We have identified SATB1, a factor

85 exhibiting enriched occupancy at gene promoters and enhancers involved in long-range chromatin

86 interactions. SATB1 has been attributed to many biological roles, mostly during T cell development

87 (Zelenka and Spilianakis, 2020), but it also regulates the function of cell types such as the epidermis

88 (Fessing et al., 2011) and neurons (Balamotis et al., 2012; Denaxa et al., 2012). Moreover, SATB1 is

89 also overexpressed in a wide array of cancers and is positively associated with increased tumour size,

90 metastasis, tumour progression, poor prognosis and reduced overall survival (Sunkara et al.,

91 2018). Originally described as a Special AT-rich Binding protein (Dickinson et al., 1992), it is known

92 for its propensity to bind DNA regions with more negative torsional stress (Ghosh et al., 2019). In a

93 proposed model, SATB1 dimers bound to DNA interact with each other to form a tetramer in order to

94 mediate long-range chromatin loops (Wang et al., 2012, 2014). The regulatory function of SATB1 is

95 controlled by post-translational modifications (Kumar et al., 2006) and indirectly also by protein-protein

96 interactions with chromatin modifying complexes (Fujii et al., 2003; Jangid et al., 2014; Kumar et al.,

97 2005; Purbey et al., 2009; Yasui et al., 2002).

98   To understand the principles of chromatin organization in murine thymocytes and their impact

99   on physiology, we performed Hi-C and HiChIP experiments and compared the roles of tissue-specific

100   SATB1 and ubiquitously expressed CTCF genome organizers. Our findings were complemented by

101   ATAC-seq, RNA-seq and H3K27ac HiChIP experiments in WT and *Satb1* cKO thymocytes to further

102   unravel the functional roles of SATB1. This represents a comprehensive genome-wide study,

103   systematically probing all SATB1-mediated chromatin loops in the T cell nucleus. A number of datasets

104   combined with unbiased analytical approaches indicated the presence of a functional organizational layer

105   built upon a general chromatin scaffold mediated by conventional genome organizers, such as CTCF,

106   specifically regulating expression of master regulator genes and adhesion molecule genes essential for

107   proper T cell development.

Results
108

Detection of regulatory chromatin loops in T cells
109

110   In order to unravel the active promoter-enhancer connectome in T cells, we performed H3K27ac HiChIP

111   experiments (Mumbach et al., 2016) in C57BL/6J (WT) thymocytes. Loop calling at 5 kbp resolution

112   (FDR ≤ 0.01) yielded 16,458 regulatory loops. To identify the prospective protein factors associated with

113   these regulatory loops, we intersected the anchors of these loops with all the available murine ChIP-seq

114   datasets from blood cells, using the enrichment analysis of ChIP-Atlas (Oki et al., 2018). The most highly

115   enriched protein factors included RAG1, RAG2, BCL11b, SATB1 and TCF1 (Figure 1A). Both RAG1/2

116   proteins are known to be associated with the H3K27ac histone modification (Maman et al., 2016; Teng

117   et al., 2015), however their main known role relies in the recombination of B and T cell receptor loci

118   (Fugmann et al., 2000). BCL11b and TCF1 are well-studied factors specifying T cell lineage

119   commitment, whose roles in forming the chromatin landscape in T cells have been recently addressed

120   (Emmanuel et al., 2018; Garcia-Perez et al., 2020; Hu et al., 2018; Johnson et al., 2018). We drew our

121   attention to SATB1, which displayed significant enrichment at the H3K27ac loop anchors (Figure 1B)

122 and also represents a known genome organizer (Cai et al., 2003, 2006), yet with a limited number of

123 genome-wide studies targeting its role in 3D chromatin organization of T cells.

The ablation of SATB1 from murine T cells leads to autoimmunity

125 In order to link the molecular mechanisms governing T cell chromatin organization to physiology, we

126 generated a $Satb1^{fl/fl}Cd4$-Cre$^+$ ($Satb1$ cKO) conditional knockout mouse and characterized its phenotype.

127 The knockout animals displayed problems with their skin and fur, inflammation in various tissues and

128 affected lymphoid organs (Figure S1A). The thymi of $Satb1$ cKO animals were smaller in size, unlike

129 their enlarged peripheral lymphoid organs. Thymic deregulation was also reflected in the impaired

130 developmental processes in the thymus as demonstrated by the deregulation of T cell populations (Figure

131 1C and S1B). The increased number of CD4$^+$CD8$^+$ (double positive - DP) cells and the decreased

132 numbers of CD4$^+$ and CD8$^+$ single positive (SP) cells in the thymus of $Satb1$ cKO mice indicated a

133 developmental blockade at the DP stage, pointing to altered positive selection as previously suggested

134 (Alvarez et al., 2000; Kondo et al., 2016). Moreover, there was a diminished pool of naïve

135 CD62L^{hi}CD44^{lo} peripheral T cells and an increased fraction of CD44^{hi} T cells displaying an activated

136 (and/or memory) T cell phenotype (Figure 1C). Deregulation of the thymic developmental programs was

137 also supported by the altered cytokine milieu in the blood serum, with prevailing IL-17 cell responses

138 and increased levels of pro-inflammatory cytokines such as IFNγ and TNFα detected in $Satb1$ cKO sera

139 (Figure 1D). The increased levels of DP T cells in the spleen (Figure 1C), together with the absence of

140 naïve CD4$^+$ T cells were suggestive of an autoimmune-like phenotype (Sakaguchi et al., 2008). Indeed,

141 we observed infiltration of T cells in the pancreas of the $Satb1$ cKO animals, causing damage to the islets

142 of Langerhans and leading to impaired glucose metabolism (Figure 1E). The deregulation of cellular

143 immunity was accompanied by the presence of autoantibodies, which we demonstrated by incubating

144 sections of WT pancreas with $Satb1$ cKO sera (Figure 1F) and $Satb1$ cKO sections of pancreas and lungs

145 with $Satb1$ cKO sera (Figure S1C). Based on these findings, we concluded that SATB1 absence leads to

146 impaired thymocyte development and the concomitant deregulation of T cell populations in the

147 secondary lymphoid organs, affecting T cell homeostasis and sustaining an autoimmune-like phenotype.

Roles of SATB1 and CTCF in T cell chromatin organization

149 SATB1 has been previously attributed with genome organizing functions (Cai et al., 2003, 2006),

150 therefore we aimed to investigate the potential deregulation of thymocyte genome organization that is

151 anticipated upon SATB1 depletion and link it to the deregulation of immune physiology we observed in

152 the *Satb1* cKO mice. For this purpose, we performed Hi-C experiments (Lieberman-Aiden et al., 2009)

153 in both WT and *Satb1* cKO thymocytes (Table S1). We did not identify any major changes in high-order

154 chromatin organization (Figure 2A). Differential analysis of topologically associating domains (TADs)

155 between WT and *Satb1* cKO cells also supported this claim with an average of 77% unchanged TADs

156 between WT and *Satb1* cKO, resembling the level of differences being usually detected between the

157 different biological replicates of the same experiment (Figure S1D; Dixon et al., 2012; Rao et al., 2014;

158 Sauerwald et al., 2020). Even though broad scale differences were not observed in the Hi-C maps, one

159 may interrogate more localized conformational changes with HiChIP data, especially given our

160 underlying hypothesis of transcription factor-guided genome organization. Therefore, we next compared

161 the SATB1-mediated and CTCF-mediated chromatin loops by performing HiChIP experiments targeting

162 the respective factors in WT cells. Our HiChIP datasets at 5 kbp resolution (FDR ≤ 0.01) yielded 1,374

163 and 3,029 loops for SATB1 and CTCF, respectively (Table S1, S2). It is important to note that in the

164 SATB1 HiChIP experiments we used custom-made antibodies specifically targeting the long SATB1

165 isoform that we recently characterized (Zelenka et al., Submitted; Table S3). We compared differentially

166 interacting areas of the HiChIP matrices at 100 kbp and 500 kbp resolution (Figure 2B). At 100 kbp

167 resolution, 46 interaction pairs were stronger in the SATB1 contact matrix compared to 553 in the CTCF

168 matrix (FDR ≤ 0.05). The analysis at 500 kbp resolution indicated a similar disproportion (7 vs 42),

169 collectively suggesting that CTCF contributes to the high-order chromatin organization in developing T

170 cells to a much higher extent than SATB1. Next, we performed aggregate peak analysis (APA; Rao et

8

171   al., 2014) applying the SATB1/CTCF-mediated HiChIP loops on Hi-C datasets derived from WT and

172   *Satb1* cKO thymocytes. As expected, this analysis unraveled diminished interactions for the SATB1-

173   mediated loops in the *Satb1* cKO cells compared to WT, but no change was evident for the CTCF-

174   mediated loops (Figure S1E). Together with the unchanged RNA levels of *Ctcf* in the *Satb1* cKO, this

175   suggested that CTCF was capable of maintaining the high-order chromatin structure in the *Satb1* cKO

176   cells. Moreover, genes residing in both CTCF- and SATB1-mediated loops were transcriptionally

177   insulated from their gene neighbors (Figure S1F) and this characteristic was not altered in the *Satb1* cKO.

178   The latter was not surprising since out of 1,374 SATB1-mediated loops, the vast majority (84%)

179   overlapped with at least one CTCF-mediated loop (Figure 2C). An overlap score, calculated by dividing

180   the length of the overlap by the total size of a loop, indicated that most of SATB1-mediated loops were

181   engulfed within CTCF loops (Figure 2D). As CTCF is a well-characterized protein with insulator

182   function (Phillips and Corces, 2009), it is likely that the transcriptional insulation effect of SATB1 was

183   derived from the CTCF function. Nevertheless; the binding pattern of these factors was quite different.

184   Similar to previously published results (Ghosh et al., 2019), the SATB1 binding sites we have identified,

185   evinced a nucleosome preference, unlike CTCF (Figure 2E). Gene ontology analysis of the genes

186   intersecting with loop anchors uncovered the high propensity of SATB1 to participate in the loopscape

187   structure of immune-related genes, while CTCF-mediated chromatin loops exhibited omnipresent

188   looping patterns resulting in the enrichment of general metabolic and cellular processes (Figure 2F).

189   Taking these results under consideration we conclude that the high-order chromatin organization of

190   murine thymocytes is primarily maintained via CTCF long-range chromatin interactions with minor input

191   from the SATB1-mediated loops.

192   **The regulatory role of SATB1-mediated chromatin loops in murine T cells**

193   To unravel the regulatory potential of SATB1-mediated chromatin loops we investigated the impact of

194   SATB1 depletion in *Satb1* cKO thymocytes. These cells generally appeared to have more compact

195   chromatin as demonstrated by several measures. Immunofluorescence experiments displayed more

9

196 intense HP1α staining (marker of heterochromatin) in *Satb1* cKO thymocytes (Figure 3A). Despite the

197 gross similarities at the higher order chromatin structure between WT and *Satb1* cKO cells, as deduced

198 by Hi-C, we have detected 1.11% of chromosome compartments that turned from compartment A

199 (predominantly consisting of euchromatin) to compartment B (heterochromatin regions; Lieberman-

200 Aiden et al., 2009) in the *Satb1* cKO cells, compared to 0.59% of B to A compartment switch (Figure

201 S1G). Genes affected by the aforementioned A-to-B compartment switch did not display any gene

202 ontology pathway enrichment which would otherwise be indicative of a link between high-order

203 chromatin structure and the deregulated immune system in *Satb1* cKO animals. This observation further

204 reinforced our hypothesis that SATB1 acts at a finer-scale level of genome organization. In addition,

205 *Satb1* cKO cells evinced a higher fraction of less accessible regions (6,389 compared to 5,114 more

206 accessible regions; p ≤ 0.01) based on ATAC-seq analysis performed for WT and *Satb1* cKO thymocytes

207 (Figure S1H; Table S4). To determine whether these chromatin accessibility changes were also reflected

208 at the transcriptional level, we performed stranded total RNA sequencing. Our analysis revealed that 922

209 genes were significantly underexpressed and 719 genes were significantly overexpressed in the *Satb1*

210 cKO compared to WT thymocytes (FDR<0.05; Table S5). Such a strong deregulation of the

211 transcriptional landscape in *Satb1* cKO cells in contrast to the modest transcriptional changes observed

212 upon depletion of conventional genome organizers (Nora et al., 2017; Rao et al., 2017; Schwarzer et al.,

213 2017) emphasizes the regulatory importance of SATB1-dependent chromatin organization.

214 SATB1 is known for its functional ambiguity of acting either as a transcriptional activator or a

215 repressor, depending on the cellular context (Kumar et al., 2006). Although the original studies were

216 mainly focused on its repressive roles (Kohwi Shigematsu et al., 1997; Liu et al., 1997; Seo et al., 2005),

217 our aforementioned observations supported the increased chromatin compactness and subsequent

218 repressed environment of the SATB1-depleted cells. This rather indicated its positive impact on

219 transcriptional gene regulation. The vast majority of SATB1 binding sites in WT thymocytes evinced

220 increased chromatin accessibility compared to randomly shuffled binding sites (i.e. what would be

10

221   expected by chance, 100 randomizations used, bootstrap p-value = 0; Figure 3B), with a visible drop in

222   chromatin accessibility in the *Satb1* cKO (Figure 3C). This drop in chromatin accessibility in *Satb1* cKO

223   cells was especially evident at the transcription start site of genes (TSS), suggesting a direct role of

224   SATB1 in gene transcription regulation (Figure 3D and S1I). Moreover, the expression changes of

225   significantly deregulated genes were positively correlated with the changes of chromatin accessibility at

226   promoters determined by ATAC-seq (Spearman's $\rho = 0.438$, $P < 2.22e{-}16$; Figure S1J). Only about 5%

227   of SATB1 binding sites had low chromatin accessibility in WT (lower than the average accessibility

228   score of ten randomizations depicted in Figure 3B). These regions had increased chromatin accessibility

229   in the *Satb1* cKO (Figure S1K), which would suggest a repressive function of SATB1. However, these

230   regions were not enriched for immune-related genes (not shown) and thus probably not contributing to

231   the observed phenotype.

232   We have next created a linear regression model, as an unbiased way to identify how gene

233   expression was affected in murine thymocytes upon SATB1 depletion. We utilized SATB1 binding,

234   SATB1- and CTCF-mediated chromatin loops, changes in H3K27ac-dependent chromatin loops and

235   changes in chromatin accessibility at different positions of a gene, as predictors of RNA level changes

236   between WT and *Satb1* cKO cells. We found that the majority of predictors exhibited an expected

237   behavior, such as increased chromatin accessibility at gene promoters was associated with increased gene

238   expression (Figure S2). The regression model highlighted SATB1 binding and SATB1-mediated

239   chromatin loops as good predictors associated with decreased RNA levels of influenced genes in the

240   *Satb1* cKO. In this analysis, we applied the model for all known genes, which resulted in a quite low R-

241   squared value (0.113). For this reason, we verified the activatory role of SATB1 loops with an additional

242   approach. We constructed an inference tree, where we systematically probed the distribution of gene

243   expression for the genes that were or were not found in SATB1-mediated loops (Figure 3E). Genes

244   located in SATB1-mediated loops displayed lower RNA levels in the *Satb1* cKO, an effect that was

11

245   further intensified when the gene was connected to an enhancer (Figure 3E), suggesting a positive role

246   for SATB1 in gene transcription via promoter-enhancer mediated chromatin loops.

247   Thymic enhancers were previously shown to be occupied by conventional genome organizers

248   such as CTCF and cohesin, suggesting their involvement in gene regulatory loops of thymocytes (Ing-

249   Simmons et al., 2015; Seitan et al., 2013). We utilized a list of predicted thymic enhancers (Shen et al.,

250   2012) and we found more than 2-fold enrichment of SATB1- over CTCF-mediated loops overlapping

251   with such enhancers (Figure S1L) and more than 3-fold enrichment of genes connected to enhancers by

252   SATB1-mediated chromatin loops over CTCF-mediated loops (Figure 3F). SATB1-mediated loops

253   connected to enhancers, also displayed a disturbed chromatin interaction pattern in *Satb1* cKO Hi-C data

254   compared to WT (Figure 3G). Collectively, these findings suggested that CTCF participates in

255   mechanisms responsible for supporting a basal high-order T cell chromatin structure, whereupon SATB1

256   likely exerts its action in a more refined organization layer consisting of promoter-enhancer chromatin

257   loops.

258   **Deregulated promoter-enhancer loops in *Satb1* cKO T cells**

259   To further investigate the latter hypothesis, we compared the promoter-enhancer chromatin loops present

260   in WT and *Satb1* cKO thymocytes, utilizing the H3K27ac HiChIP loops. H3K27ac HiChIP in *Satb1* cKO

261   thymocytes yielded 19,498 loops (compared to 16,458 loops detected in WT; Table S1, S2). Differential

262   analysis of the 3D interactions (independent on the 1D H3K27ac ChIP-seq signal) identified 11,540 and

263   12,111 H3K27ac loops displaying decreased or increased contact enrichment in the *Satb1* cKO compared

264   to WT cells, respectively (further referred as "underinteracting" and "overinteracting" H3K27ac loops,

265   respectively; Table S6). The RNA levels of the genes associated with differential H3K27ac chromatin

266   loops in WT versus *Satb1* cKO displayed a positive correlation (Spearman's $\rho = 0.26$) with the difference

267   between over- and under-interacting H3K27ac loops (Figure 4A). The SATB1-mediated

268   underinteracting H3K27ac loops displayed the highest drop in the RNA levels of the overlapping genes

269   compared to those in non-SATB1 underinteracting H3K27ac loops (Figure 4B). In contrast, the genes

270   localized in anchors of overinteracting H3K27ac loops did not show any major changes in expression

271   (Figure 4C). Moreover, the expression of genes located at anchors of SATB1-mediated loops was

272   decreased more dramatically than genes located at CTCF loops (Figure 4B). This finding is a good

273   indication of causality, supporting direct involvement of SATB1 in the regulatory chromatin loops.

274   Next, we sought to investigate the genes intersecting with anchors of the differential H3K27ac

275   loops. Underinteracting H3K27ac loops, with the highest score, included genes encoding for master

276   regulators and T cell signature genes such as *Bcl6*, *Ets2*, *Tcf7*, *Cd8b1*, *Ikzf1*, *Bach2*, *Cd6*, *Rag2*, *Il4ra*,

277   *Rag1*, *Lef1* and others (in descending order; Table S6), which all evinced decreased RNA levels in the

278   *Satb1* cKO. On the other hand, the overinteracting H3K27ac loops with the highest score also contained

279   factors essential for proper T cell development and differentiation such as *Tox*, *Gata3*, *Ifngr1, Maf* and/or

280   *Jun* (Table S6), which all correspondingly displayed increased gene expression in the *Satb1* cKO

281   thymocytes. Certain genes present in the overinteracting H3K27ac loops were bound by SATB1 and a

282   fraction of them were also found in SATB1-mediated loops. Thus, we cannot exclude the possibility that

283   SATB1 mediates a repressive role for these targets. Though, since our unbiased approaches have

284   primarily suggested an activatory role for the SATB1-mediated loops, in this work we focused on this.

285   **SATB1 positively regulates *Bcl6* and other master regulator genes**

286   The most highly affected candidate gene, in terms of H3K27ac underinteracting loops in the *Satb1* cKO

287   compared to WT, was *Bcl6*. The expression of *Bcl6* gene in B cells is regulated by a set of super-

288   enhancers; one spanning the promoter and 5' UTR region, and additional three distal upstream enhancer

289   stretches at 150-250 kbp, ~350 kbp and at ~500 kbp (Chapuy et al., 2013; Qian et al., 2014;

290   Ramachandrareddy et al., 2010; Ryan et al., 2015). Apart from H3K27ac differential loops, we identified

291   increased SATB1-mediated interactions in the locus with two significant SATB1-mediated loops

292   connecting *Bcl6* and the super-enhancer regions at ~250 kbp and ~500 kbp upstream of the gene (Figure

293   4D; here referred to as SE1 and SE2, respectively). These enriched chromatin interactions observed in

294   WT were absent in the *Satb1* cKO thymocytes as deduced by Hi-C experiments (red arrows). As a result

295   of this deregulation, the *Bcl6* gene displayed significantly lower RNA levels in the *Satb1* cKO

296   thymocytes (log2FC = –1.290, FDR = 5.6E–10). Next, we utilized this gene locus as an example for 3D

297   modeling experiments. Initially, we utilized our CTCF and SATB1 HiChIP data and performed

298   computational modeling which supported the idea that SATB1-mediated chromatin landscape

299   represented a regulatory layer, built on a generic scaffold mediated by other factors, at least partly by

300   CTCF (Figure S3A). 3D modeling based on Hi-C data allowed us to better visualize the differences in

301   the proximity between *Bcl6* and its super-enhancers in WT and *Satb1* cKO cells (Figure 4E). To further

302   support the functional significance of these interactions, we overlaid these models with ChIP-seq data

303   for the histone modifications H3K27ac, H3K4me1 and H3K4me3 from WT cells (Figure S3B). These

304   models showed that active enhancers decorated by H3K27ac and H3K4me1 were located in spatial

305   proximity to *Bcl6* gene in WT and not in *Satb1* cKO cells. It is worth noting that 1D H3K27ac ChIP-seq

306   peaks derived from HiChIP experiments available for WT and *Satb1* cKO did not reveal any major

307   differences between the genotypes, which further reinforces the importance of SATB1-mediated 3D

308   chromatin organization regulating *Bcl6* expression. 3D modeling, based on thymocyte Hi-C datasets,

309   allowed us to untangle the potential presence of discrete cell subpopulations. In WT animals, we

310   identified two subpopulations of cells differing in the proximity between *Bcl6* and its super-enhancers

311   (Figure S3C); yet no significant subpopulation formation was detectable in the *Satb1* cKO. BCL6 is the

312   master regulator of Tfh cell lineage specification during the differentiation of naive CD4 cells into Tfh

313   cells (Johnston et al., 2009; Nurieva et al., 2009; Yu et al., 2009). However, it is also expressed in

314   developing thymocytes (Hyjek et al., 2001; Sun et al., 2000) where it was shown to form a complex with

315   E3 ubiquitin ligase CUL3 and exert a negative feedback loop on the Tfh program by repressing *Batf* and

316   *Bcl6* (Mathew et al., 2014). Thus, we speculated that the different subpopulations identified in our 3D

317   modeling may be linked to the different developmental T cell fates, where Tfh precursor cells would

318   differ from other cell type precursors by the distance between *Bcl6* and its super-enhancers. In support

319   to the connection between SATB1-mediated regulation and Tfh lineage specification, we demonstrated

14

320 that *Satb1* cKO animals had disturbed germinal centers (Figure 4F), which translated into the production

321 of autoantibodies (Figure 1F and S1C).

322 Apart from *Bcl6*, more genes (depicted in Table S6) were also regulated by the SATB1-mediated

323 chromatin organization which are quite important for the function of the immune system. Genomic tracks

324 and SATB1-mediated HiChIP loops for such selected genes (*Tcf7*, *Lef1*, *Cd8*, *Ikzf1*, *Satb1*) are presented

325 in Figure S4.

326 **T cell receptor locus and cell adhesion in *Satb1* cKO**

327 We should note that in the differential analysis of H3K27ac loops, short genes could be underestimated,

328 hence we further considered gene length in our analysis. Indeed, upon taking this into account, the most

329 affected genes in both categories of overinteracting and underinteracting loops were enriched for gene

330 segments of the T cell receptor (TCR) locus (Table S6).

331 TCR is the most important cell surface receptor expressed in thymocytes which defines multiple

332 developmental decisions. The generation of a functional TCR involves recombination of the variable

333 (V), diversity (D) and joining (J) gene segments via a process called V(D)J recombination. This process

334 is based upon the action of protein complexes that include RAG1 and RAG2 recombinases (Fugmann et

335 al., 2000). Recruitment of RAG proteins is highly correlated with active promoters labeled with

336 H3K4me3 (Ji et al., 2010; Teng et al., 2015) and also with enhancers and regions decorated by the

337 H3K27ac mark (Maman et al., 2016; Teng et al., 2015). Moreover, recombination is regulated by the 3D

338 organization of the locus driven by the architectural proteins CTCF and cohesin, mainly via the

339 arrangement of specific TCR enhancers (Chen et al., 2015; Seitan et al., 2011; Shih et al., 2012).

340 Here, we revealed a number of SATB1-mediated loops connecting the TCRα enhancer with inner

341 regions of the locus (Figure 5A). Moreover; a number of highly significant SATB1 loops split the region

342 of joining gene segments into two parts – one part containing gene segments that were overexpressed

343 and the other half containing gene segments that were underexpressed in the *Satb1* cKO. This resulted in

344 the defective usage of the TCRα joining segments (Figure 5A), coupled with the overall *Tcra*

15

345   rearrangement in *Satb1* cKO animals as previously reported (Feng et al., 2021; Hao et al., 2015). A

346   previous study ascribed this deregulation to the lost SATB1-mediated regulatory loops, positively

347   controlling the expression of both *Rag1*/*Rag2* genes resulting in lower levels of RAG proteins (Hao et

348   al., 2015). We validated the presence of these regulatory loops (Figure 5B) as well as the resulting 2-fold

349   and 2.8-fold decrease in thymic RNA levels of the *Rag1* and *Rag2* genes (Figure 5C), respectively (which

350   was less profound in sorted DP cells: 1.34-fold and 1.61-fold decrease for *Rag1* and *Rag2* genes,

351   respectively; data not shown). However, given the long turnover of RAG proteins, their thymic protein

352   levels were not significantly affected (Figure 5D). Moreover, the representation of *Traj* fragments was

353   correlated with the presence of overinteracting and underinteracting H3K27ac loops (Figure 5E),

354   indicating the importance of 3D chromatin organization of the TCR locus in its rearrangements.

355   Apart from the deregulation of H3K27ac chromatin loops in *Satb1* cKO compared to WT

356   thymocytes, as deduced by HiChIP experiments we should also note that the "cell adhesion pathway"

357   was overrepresented in gene ontology analysis for both underexpressed genes by RNA-seq and genes

358   associated with less accessible regions as deduced by ATAC-seq (Figure 6A; gene ontology pathways

359   for other genomic datasets are presented in Figure S5). Indeed, genes encoding key molecules for

360   intrathymic crosstalk (Lopes et al., 2015) were underexpressed in the *Satb1* cKO (Figure 6B). In addition

361   to the deregulated loopscape structure of the TCRα gene locus, we identified similar defects in the

362   SATB1-mediated regulatory looping for adhesion molecule gene loci such as *Cd28* (Figure 6C), *Lta*, *Ltb*

363   (Figure S6A) and *Ccr7* (Figure S6B). Total thymocyte RNA sequencing revealed the downregulation in

364   expression levels of receptors specific for the medullary thymic epithelial cells (Figure 6B). In support

365   of this finding, we also identified the disrupted thymic structure and impaired cell-to-cell communication

366   in the *Satb1* cKO thymus. This deregulation was notable from several histological and electron

367   microscopy experiments indicating disrupted cellular contacts in *Satb1* cKO (Figure 6D). As a result, the

368   thymi of *Satb1* cKO animals contained a lower number of cells (Figure 6E), partly due to the increased

16

369 apoptosis rate (Figure 6F) resulting from the impaired developmental pathways and partly due to the

370 increased exit rate of these improperly developed T cells from the thymus (Figure 6G).

Discussion

372 The adaptive immune response relies on the accurate developmental coordination of several alternative

373 cell lineage fates. 3D genome organization in T cells represents a crucial denominator for this

374 coordination (Spilianakis and Flavell, 2004; Spilianakis et al., 2005). In this work, we described the

375 regulatory chromatin network of developing T cells and identified SATB1 protein being enriched at the

376 anchors of regulatory chromatin loops. We performed a systematic genome-wide analysis of SATB1

377 roles in T cells. First, we compared the chromatin organization role of SATB1, to that of the conventional

378 genome organizer CTCF. Utilizing a plethora of research approaches, we demonstrated that SATB1

379 establishes a finer-scale organizational layer, built upon the pre-existing scaffold mediated by other

380 architectural proteins. Depletion of conventional genome organizers such as CTCF (Nora et al., 2017) or

381 cohesin (Rao et al., 2017; Schwarzer et al., 2017) resulted in vast deregulation of TADs, however it did

382 not show dramatic changes in gene expression as one would expect. On the contrary, SATB1 depletion

383 did not result in any changes of TADs or high order chromatin organization, yet the long-range promoter-

384 enhancer interactions were highly deregulated as well as the underlying transcriptional programs.

385 It was not clear so far whether SATB1 should be primarily assigned a role as an activator or a

386 repressor. This characteristic makes SATB1 markedly similar to the ubiquitously expressed factor YY1.

387 YY1 was also found enriched at promoters and enhancers, mediating their spatial contacts (Weintraub et

388 al., 2017); however, depending on the cellular context it has also been found in association with

389 Polycomb repressive complexes (Bracken and Helin, 2009). It would be interesting to further investigate

390 the determinants of such functional ambiguity for such factors. In our experimental setup, we have

391 demonstrated the activatory function of SATB1, in specifically mediating promoter-enhancer long-range

392 chromatin interactions. Although the repressed nuclear environment of *Satb1* cKO cells was in agreement

17

393   with those findings, we should note that in our study we were mostly focused on functions of the long

394   SATB1 protein isoform. The presence of two SATB1 protein isoforms was recently described by our

395   group (Zelenka et al., Submitted) and it could be another reason, aside from various post-translational

396   SATB1 variants (Kumar et al., 2006; Zelenka and Spilianakis, 2020), supporting its functional ambiguity.

397   We showed that the long SATB1 protein isoform had a higher propensity to undergo phase transitions

398   compared to the short isoform (Zelenka et al., Submitted). Considering the proposed model of

399   transcriptional regulation via liquid-liquid phase separated transcriptional condensates (Cho et al., 2018;

400   Sabari et al., 2018), we reasoned that even the subtle differences in biophysical properties between the

401   two SATB1 isoforms may play an important regulatory role. Following these observations, we

402   hypothesize a model in which SATB1-mediated contacts between promoters and enhancers are attracted

403   to the transcriptional condensates depending on the type and concentration of the SATB1 variants

404   present. Post-translational modifications and/or different SATB1 isoforms would therefore regulate the

405   whole process and under certain conditions, SATB1 could even function as a repressor. Thus, in

406   comparison to other transcription factors capable of mediating long-range chromatin interactions, the

407   SATB1's mode of action may include one or more mechanisms that were proposed (Giammartino et al.,

408   2020; Kim and Shendure, 2019; Stadhouders et al., 2019); i.e. via direct (Wang et al., 2012, 2014) or

409   indirect (Fujii et al., 2003; Jangid et al., 2014; Kumar et al., 2005; Purbey et al., 2009; Yasui et al., 2002)

410   oligomerization or via phase separation (Zelenka et al., Submitted). Overall, the presence of proteins like

411   SATB1 with tissue-restricted expression profile, may represent the missing link between chromatin

412   organization and tissue-specific transcriptional regulation.

413   One of our goals was to provide molecular mechanisms such as the 3D chromatin organization

414   of T cells in order to explain the phenotypical malformations observed in the *Satb1* cKO mice. *Satb1*-

415   deficient mice suffer from multiple health problems, markedly resembling autoimmunity. Previous

416   research suggested a cell-extrinsic mechanism of autoimmunity based on the deregulation of regulatory

417   T cells (Kitagawa et al., 2017). Here we presented that SATB1 is a regulator of several genes involved

418   in T cell development, such as *Bcl6*, *Tcf7*, *Lef1*, *Cd6*, *Cd8*, *Lta*, *Ltb* and others. The individual

419   deregulation of most of these genes would also result in deregulated immune responses. A great example

420   for a cell-intrinsic mechanism of autoimmunity in the *Satb1* cKO is the SATB1-mediated spatial

421   rearrangement of the TCRα enhancer and the TCR locus *per se*, controlling TCR recombination. A

422   previous study linked the deregulation of the TCRα locus identified in the *Satb1* cKO to the

423   downregulation of the *Rag1* and *Rag2* genes (Hao et al., 2015). In addition to this deregulation and the

424   SATB1-mediated regulatory loops at the *Rag* locus, we also revealed the deregulation of chromatin

425   accessibility and H3K27ac looping at the TCR locus. This was correlated with the SATB1-mediated

426   chromatin loops and ultimately the defective usage of the different TCR segments. Since the recruitment

427   of RAG proteins is based on the epigenetic status of a gene locus (Maman et al., 2016; Teng et al., 2015),

428   we hypothesized that the altered TCR organization, due to missing SATB1-mediated loops, together with

429   the disrupted recruitment of chromatin modifying complexes interacting with SATB1 (Fujii et al., 2003;

430   Jangid et al., 2014; Kumar et al., 2005; Purbey et al., 2009; Yasui et al., 2002), would be critical

431   contributors for the defective TCR arrangement in the *Satb1* cKO. Moreover, the impact of the 3D

432   organization of TCR and BCR, necessary for proper VDJ recombination was recently highlighted (Peters,

433   2021; Rogers et al., 2021).

434   Apart from the TCRα locus, the most affected gene regarding the differential interaction analysis

435   of regulatory loops between WT and *Satb1* cKO thymocytes was *Bcl6*. BCL6 represents a master

436   regulator of Tfh (Johnston et al., 2009; Nurieva et al., 2009; Yu et al., 2009) and innate-like T cells

437   (Gioulbasani et al., 2020). We have demonstrated that the Tfh program is deregulated in the *Satb1* cKO

438   utilizing several research approaches. Moreover, the blockade at stage 0 (ST0) of iNKT development in

439   *Satb1*-deficient mice was previously reported (Kakugawa et al., 2017), collectively suggesting a potential

440   link between SATB1-mediated regulation of *Bcl6* and these developmental programs. BCL6 is known

441   to function as an antagonist of factors specifying other cell lineage fates (Vinuesa et al., 2016; Wu et al.,

442   2018), especially of PRDM1 and underlying Th17 lineage specification (Johnston et al., 2009). Indeed,

19

443   the increased IL-17 response we observed in the cytokine milieu of *Satb1* cKO mouse sera (Figure 1D),

444   suggests a favored Th17 specification due to downregulation of BCL6. However, since the depletion of

445   SATB1 and its underlying regulome took place already during the intra-thymic development

446   (*Satb1*$^{\text{fl/fl}}$*Cd4*-Cre^{+}), we hypothesize that the increased IL-17 cytokine levels were primarily due to

447   potentially elevated γδT17 cells. Based on the transcriptomic analysis depicted in Figure 5A (RNA-seq,

448   WT/*Satb1* cKO) we have detected the overexpression of the TCRδ locus and correspondingly also of the

449   Vγ4^{+} and Vγ6^{+} chains which are expressed in γδT17 cells (Buus et al., 2016; Haas et al., 2012; Muñoz-

450   Ruiz et al., 2017; Papotto et al., 2017). Moreover, the most overexpressed gene in *Satb1* cKO thymocytes,

451   as indicated by our RNA-seq experiments, was *Maf* (encoding c-MAF; log2FC = 3.696 in female thymus

452   and log2FC = 7.349 in male DP cells), which was shown to be essential for the commitment of γδT17

453   cells (Zuberbuehler et al., 2019).

454   Our findings point to the regulatory overlap between TCR recombination and transcriptional

455   activity of master regulator genes in T cells, collectively orchestrated via spatial chromatin arrangements

456   controlled by SATB1 and ultimately leading to the control of developmental decisions in the thymus.

457   We provide a unique report on the functional intersection between CTCF and a tissue-specific genome

458   organizer such as SATB1. Using the link between the altered 3D enhancer network and the physiological

459   deregulation of *Satb1* cKO animals, we demonstrate the importance of the functional layer of chromatin

460   organization provided by transcription factors such as SATB1. Our goal is to stir up a discussion about

461   the existence of other tissue- or cell type-restricted factors, potentially contributing to the higher

462   complexity and direct regulatory potential of the 3D chromatin architecture.

488 **Data availability**

489   All genomics experiments are deposited in Gene Expression Omnibus database under accession

490   number GSE173476. Other datasets will be provided upon a reasonable request.

491

Methods

Animals and isolation of thymocytes

All experiments were conducted in accordance with the Laboratory Animal Care and Ethics Committee of IMBB-FORTH. Animal work was approved by the IMBB Institutional Animal Care and Ethics Committee. All the experiments were performed on mice with C57BL/6 background. The generation of *Satb1*$^{fl/fl}$ mice was previously described (Denaxa et al., 2012). The *Satb1* cKO (conditional knockout) mouse under study was created by crossing the *Satb1*$^{fl/fl}$ mouse with a *Cd4*-Cre transgenic animal. The animals used for the experiments were 4-8 weeks old, unless otherwise specified. Primary thymocytes were resuspended by rubbing and passing the thymus through a 40 µm cell strainer (Falcon, 352340) into 1X PBS buffer. Cells were washed twice with 1X PBS: cells were centrifuged at 500 g, 4°C for 5 minutes, resuspended in 10 ml of 1X PBS and both steps were repeated. Prepared thymocytes were either used directly for experiments or fixed with 1% methanol-free formaldehyde (Pierce, 28908) at room temperature (RT) for 10 minutes while rocking. To quench the reaction, glycine was added to 0.125 M final concentration and incubated at RT for 5 minutes, while rocking. Cells were centrifuged at 1,000 g, 4°C for 5 minutes and washed twice with ice cold 1X PBS.

Flow cytometry

Characterization of T cell populations in the *Satb1* cKO

Depending on the experiment, we used either thymocytes or splenocytes. Splenocytes were isolated in the same way as thymocytes, but they were further resuspended in plain water for 3 seconds to lyse erythrocytes, with immediate dilution by HBSS (Gibco, 14180) to a final 1X concentration. One million cell aliquots were distributed into 5 ml polystyrene tubes (BD Falcon 352052). For the experiments probing the percentage of apoptotic cells in tissues, we followed the PI/Annexin protocol (Biolegend, 640914). For staining with antibodies, we washed the cells once with Staining Buffer (1X PBS, 2% FBS, 0.1% NaN3) and then stained in 100 µl of Staining Buffer with 1 µl of antibodies at 4°C for 30 minutes. The stained cells were washed with excess of Wash Buffer (1X PBS, 0.5% FBS) and then analyzed on FACSCalibur flow cytometer. The antibodies used in flow cytometry experiments were anti-DNA PI-

23

518   conjugated (Biolegend-79997), anti-Phosphatidylserine FITC conjugated (Biolegend-640906), anti-CD4

519   PE conjugated (Pharmingen-553730), anti-CD8a APC conjugated (Biolegend-100712), anti-CD44 PE

520   conjugated (Pharmingen-553134) and anti-CD62L FITC conjugated (Biolegend-104406).

521   <u>Infiltration of CD4$^+$ cells in pancreas</u>

522   Pancreas was isolated from three WT and three *Satb1* cKO mice of 120-136 days of age. Pancreas was

523   cut in pieces and digested in 5 ml of 1 mg/ml collagenase (SIGMA, C2674) in PBS solution at 37°C for

524   30 minutes. Samples were washed twice with 5% FBS in PBS and filtered through a polypropylene mesh.

525   After centrifugation, cell pellets were resuspended in 1 ml of 0.05% Trypsin solution and incubated for

526   5 minutes at 37°C. Cells were washed twice with ice-cold PBS and eventually filtered through a 40 μm

527   cell strainer and blocked in 5 ml of 5% FBS in PBS for 30 minutes at 4°C. Cells were stained with 1:200

528   CD4-PE and CD8-APC for 30 minutes at 4°C and then washed twice with 0.5% FBS in 1X PBS. Lastly,

529   cells were resuspended in 2% FBS in 1X PBS and analyzed by flow cytometry.

530   **Characterization of the cytokine milieu**

531   Cytokines were characterized and quantified from serum of 16 female mice (5 WT, 11 *Satb1* cKO) of

532   varying age 1-7 months by the LEGENDplex (13-plex) Mouse Th Cytokine Panel V02 (Biolegend,

533   740741; Lot B289245) according to the manufacturer's instructions. Data were analyzed by the provided

534   software LEGENDplex 8.0.

535   **Intraperitoneal glucose tolerance test**

536   Groups of four WT and five *Satb1* cKO animals of 85 days (±8) of age were fasted for 6 hours. Weight

537   and blood glucose levels were measured before and after the fasting period. 10% dextrose solution was

538   injected intraperitoneally – the volumes were adjusted individually for each animal in order to inject 2 g

539   of dextrose per kg of body mass. Blood (taken from tail) glucose levels were measured at given time

540   points using Bayer Contour XT machine with Bayer Ascensia Contour Microfill Blood Glucose Test

541   Strips. Animals were sacrificed and their pancreas was used for histology sections to demonstrate the

542   disturbance of the islets of Langerhans.

Histology and tissue sectioning

Samples were fixed in 4% formaldehyde in 1X PBS (pH 7.4) for 12-15 hours at 4°C. Tissues were rinsed in PBS and stored in PBS at 4°C until embedding. For embedding, samples were dehydrated for 30 minutes in 70% ethanol, 2x30 minutes in 90% ethanol and 3x30 minutes in 100% ethanol – all at RT while stirring. Specimens were cleared for 2x60 minutes in xylol and then impregnated for 1-2 hours at 58°C with paraffin. Samples were positioned in embedding moulds and left overnight to harden. Samples were sectioned on a sliding microtome to achieve 5-10 μm thin sections. The prepared sections on glass slides were deparaffinized for 30 minutes at 65°C and then for 2x 30 minutes in Neo-Clear (Merck Millipore, 109843). Samples were rehydrated for 2x 10 minutes in 100% ethanol, 1x 5 minutes in 90% ethanol, 1x 5 minutes in 70% ethanol, 1x 5 minutes in 50% ethanol, 1x 5 minutes in 30% ethanol and 1x 5 minutes in 1X PBS. Samples were immersed in Haematoxylin bath for 5 minutes in dark and then washed by running water for 5-10 minutes and in 1X PBS for 1 minute. Next, samples were immersed in Eosin bath for 30 seconds in dark and then washed by running water for 5-10 minutes and in 1X PBS for 1 minute. Samples were dehydrated again by dipping ten times in 30%, 50% and 70% ethanol and then incubated for 2x2 minutes in 100% ethanol. Eventually, samples were incubated for 2x10 minutes in xylene and then mounted using Entellan® new (Merck Millipore, 107961).

Transmission electron microscopy

For scanning electron microscopy (SEM), fresh thymi were cut into small blocks. Briefly, tissue was fixed for 2 hours with 2% paraformaldehyde – 2% glutaraldehyde in 0.1 M sodium cacodylate buffer. Samples were post-fixed overnight in 1% osmium tetroxide (OTO method) and dehydrated in a graded series of ethanol. Specimens were coated in gold, mounted on aluminum stubs and examined with a JEOL JSM6390 LV scanning electron microscope (Peabody, MA) using an accelerating voltage of 15 kV.

Detection of autoantibodies

The WT pancreas sample was prepared as previously described. 5 μm thick sections were deparaffinized at 55°C for 8 min and then processed in the following solutions: 2x 3 minutes in Neo-Clear, 2x 3 minutes

25

569   in 100% ethanol, 1x 3 minutes in 95% ethanol, 1x 3 minutes in 70% ethanol, 1x 3 minutes in 50% ethanol.

570   Samples were then rinsed with water and carefully dried with a paper towel. Tissue was circled with a

571   PAP pen, let dry for 1 minute and then dipped in PBS for 2 minutes. Antigens were retrieved by

572   incubation with 130 µl of TE-Triton-PK solution (2 ml TE buffer, 10 µl 0.5% Triton X-100, 40 µg

573   Proteinase K) in a humidified chamber at 37°C, for 12 minutes. Samples were then washed twice with

574   TBST buffer (10 mM Tris-HCl – pH 8.0, 150 mM NaCl, 0.05% Tween-20) for 3 minutes each. Samples

575   were blocked by incubation with 5% normal goat serum (NGS) in TBST buffer at RT for 30 minutes in

576   a humidified chamber. Samples were incubated at 4°C overnight with blood serum collected from two

577   WT and four *Satb1* cKO animals of 4-7 months of age. Serum was diluted 1:10 in 5% NGS-TBST and

578   5% NGS-TBST was used as a negative control. Samples were washed twice with TBST, 5 minutes each.

579   Samples were incubated with a goat anti-mouse IgG antibody (H+L; Invitrogen, A-11032) conjugated

580   with Alexa Fluor 594, diluted 1:500 in TBST at RT for 1 hour. Samples were washed three times, 5

581   minutes each, with TBST and incubated with 1 µM DAPI solution in 5% NGS-TBST at RT for 10

582   minutes. Samples were washed three times, 5 minutes each, with TBST and mounted with Mowiol on

583   glass slides.

584   **Hi-C and HiChIP experiments**

585   <u>Generation of proximity-ligated contacts</u>

586   A biological duplicate was used for each sample. Both Hi-C and HiChIP experiments were performed

587   identically until the chromatin immunoprecipitation step. Aliquots of 10 million isolated thymocytes

588   resuspended in 1X PBS were fixed by adding 1/10th volume of fixation butter [11% methanol-free

589   formaldehyde (Pierce, 28908), 100 mM NaCl, 1 mM EDTA, 0.5 mM EGTA, 50 mM Hepes pH 8.0] with

590   rocking at RT for 10 minutes. To quench the reaction, glycine was added to 0.125 M final concentration

591   and incubated at RT for 5 minutes, while rocking. After two washes with 1X PBS, cell pellet was

592   resuspended in 500 µl of ice-cold Hi-C Lysis Buffer (10 mM Tris-HCl – pH 8, 10 mM NaCl, 0.2% NP40,

593   0.5 mM PMSF) and rotated at 4°C for 1.5 hours. Cells were centrifuged at 2,500 g, at 4°C for 5 minutes

594   and the supernatant was discarded. The cell pellet was washed once with 500 µl of ice-cold Hi-C Lysis

26

595   Buffer and then resuspended in 100 µl of 0.5% SDS. Cells were incubated at 62 °C for 10 minutes and

596   then combined with 296 µl of H2O and 50 µl of 20% Triton X-100. Samples were incubated at 37°C for

597   15 minutes and then combined with 50 µl of 10X DpnII Buffer and 200 U of DpnII restriction enzyme

598   (NEB, R0543M) and digested for additional 16 hours at 37 °C while shaking (160 rpm). The restriction

599   enzyme was inactivated at 62°C for 20 minutes and the nuclei were centrifuged at 2,500 g, at 4 °C for 6

600   minutes. The supernatant was discarded and the nuclei were resuspended in 300 µl Fill-in Buffer

601   containing 30 µl Klenow Buffer 10X (NEB, M0210L), 15 µl1 mM Biotin-16-dCTP (Jena Bioscience,

602   NU-809-BIO16-L), 1.5 µl 10 mM dATP (Promega, U1240), 1.5 µl 10 mM dGTP (Promega, U1240), 1.5

603   µl 10 mM dTTP (Promega, U1240), 12 µl 5 U/µl DNA Polymerase I, Klenow Fragment (NEB, M0210L)

604   and 238.5 µl water. The biotinylation mixture was incubated at 37°C for 30 minutes with rotation. SDS

605   was added to a final concentration of 0.5% to inactivate the Klenow enzyme. Triton X-100 was added to

606   1% final concentration and samples were incubated at 37°C for 5 minutes. Samples were centrifuged at

607   2,500 g, at 4 °C for 10 minutes and the supernatant was discarded. The nuclei pellet was resuspended in

608   the Ligation Buffer containing 120 µl 10X NEB T4 DNA Ligase Buffer supplemented with 10 mM ATP

609   (NEB, B0202), 60 µl 20% Triton X-100 (1% final), 6 µl 2% (20 mg/ml) BSA, 40 µl 30% PEG 6,000

610   (1% final), 5 µl 400 U/µl T4 DNA Ligase (NEB, M0202L) and 969 µl water. The samples were incubated

611   for 6 hours at RT with mild rotation. Nuclei were centrifuged at 2,400 g, at RT for 15 minutes and the

612   supernatant was discarded. The pellet was resuspended in 60 µl Lysis Buffer (1% SDS, 50 mM Tris-HCl

613   – pH 8, 20 mM EDTA, 1X protease inhibitors) and incubated at RT for 15 minutes. The lysate was

614   diluted to 600 µl using ice cold TE Buffer supplemented with protease inhibitors and then sonicated with

615   a Labsonic M – Tip sonicator for 3 cycles (30 seconds ON/OFF, 40% power). The sonicated material

616   was centrifuged at 16,000 g, at RT for 15 minutes and the supernatant was collected into a new tube.

617   Samples from the same genotype were merged and then split again: separately 100 µl for Hi-C and 450

618   µl for HiChIP.

27

619   **Hi-C** samples were combined with two volumes of Hi-C Elution Buffer (10 mM Tris-HCl – pH 8, 5 mM

620   EDTA, 300 mM NaCl, 1% SDS) and incubated at 65°C overnight. Decrosslinked material was diluted

621   to 500 μl with TE Buffer and treated with RNase A and Proteinase K as previously described. DNA was

622   purified using a ChIP DNA Clean & Concentrator kit following the manufacturer's instructions (Zymo

623   Research, D5205). Purified DNA was quantified using Qubit dsDNA BS Assay Kit (Invitrogen, Q32853)

624   checked on an agarose gel for shearing efficiency and 100 μg were used for library construction.

625   **HiChIP** samples were combined with Triton X-100 to 1% final concentration and samples were

626   incubated at 37°C for 15 minutes. Samples were combined with an equal volume of 2X ChIP Binding

627   Buffer (20 mM Tris-HCl – pH 8, 2 mM EDTA, 0.2 % sodium deoxycholate, 2X protease inhibitors).

628   Chromatin preclearing and antibody binding to magnetic beads were performed as described in the ChIP

629   protocol. The following antibodies were used for the immunoprecipitation step: 8 μg of custom-made

630   David's Biotechnologies SATB1 long isoform, 7 μg Abcam (ab70303) anti-CTCF and 2 μg Abcam

631   (ab4729) anti-H3K27ac.

632   Antibody-coupled beads were incubated with chromatin at 4°C with rotation for 16 hours. Beads

633   were washed five times with ice cold RIPA Buffer (50 mM Hepes pH 8, 1% NP-40, 0.70% Na-

634   Deoxycholate, 0.5 M LiCl, 1 mM EDTA, protease inhibitors) and then twice with TE Buffer. After the

635   first wash with TE Buffer, resuspended beads were transferred into a new tube. Immune complexes

636   bound to beads were eluted in 125 μl Hi-C Elution Buffer (10 mM Tris-HCl – pH 8, 5 mM EDTA, 300

637   mM NaCl, 1% SDS) at 65°C for 16 hours. Decrosslinked material was diluted to 250 μl with TE Buffer

638   and treated with RNase A and Proteinase K as previously described. DNA was purified using a ChIP

639   DNA Clean & Concentrator kit following the manufacturer's instructions (Zymo Research, D5205).

640   Purified DNA was quantified using Qubit dsDNA HS Assay Kit (Invitrogen, Q32854) and used for

641   library construction.

642   Biotin pull-down and library construction

28

643   Samples were brought to 25 μl with water. 5 μl and 20 μl for HiChIP / Hi-C samples, respectively, of

644   Dynabeads MyOne Streptavidin C1 beads (Invitrogen, 65001) were washed with 500 μl Tween Wash

645   Buffer (5 mM Tris-HCl – pH 7.5, 0.5 mM EDTA, 1 M NaCl, 0.05% Tween-20). Beads were resuspended

646   in 25 μl of 2X Biotin Binding Buffer (10 mM Tris-HCl – pH 7.5, 1 mM EDTA, 2M NaCl) and combined

647   with samples. Samples were incubated at RT for 20 minutes. Beads were separated on a magnet and

648   washed twice with 400 μl of Tween Wash Buffer. Beads were washed by 100 μl of 1X TD Buffer (10

649   mM Tris-HCl – pH 7.5, 5 mM MgCl$_2$, 10% Dimethylformamide). Beads were resuspended in 25 μl of

650   2X TD Buffer and combined with Tn5 enzyme from the Nextera DNA Sample Preparation Kit (Illumina,

651   FC-121-1030) and water to final volume 50 μl. The amount of Tn5 enzyme was adjusted according to

652   the input DNA amount: 4.5 μl for Hi-C libraries, 1.5 μl for SATB1 HiChIP and 1 μl for other HiChIP

653   libraries. The reaction was incubated at 55°C for 10 minutes. The beads were collected with a magnet

654   and the supernatant was discarded. Beads were resuspended in 300 μl of Strip Buffer (0.15% SDS, 10

655   mM Tris-HCl – pH 8, 50 mM EDTA) and incubated for 5 minutes at RT to strip off and deactivate Tn5.

656   Beads were washed once with 400 μl of Tween Wash Buffer and once with 500 μl of 10 mM Tris-HCl

657   (pH 8.0). The beads were resuspended in 50 μl of the following PCR master mix with indexed primers

658   from the Nextera DNA Sample Preparation Index Kit (Illumina, FC-121-1011): Phusion HF 2X (NEB,

659   M0531L) 25 μl, Nextera Index 1 (N7XX 5.5 μM) 1 μl (1.5 for Hi-C), Nextera Index 2 (N5XX 5.5 μM)

660   1 μl (1.5 for Hi-C) and water 23 μl (22 for Hi-C). The PCR reaction was performed following the program

661   72°C for 5 minutes and repeated cycles of 98°C for 15 seconds, 63 °C for 35 seconds, 72 °C for 1 minute.

662   The number of PCR cycles was estimated based on post-ChIP quantification and amplification was 6

663   cycles for Hi-C libraries, 11 cycles for SATB1 HiChIP and 13 cycles for the other HiChIP libraries. DNA

664   libraries were purified and size-selected using AMPure XP beads, quantified by Qubit and analyzed on

665   a Bioanalyzer, as previously described. The DNA Libraries were sequenced on an Illumina® HiSeq 4000

666   2x 75 bp platform by the sequencing facility at IKMB, Kiel University, Germany.

667   <u>Data processing</u>

29

668 Raw reads were mapped with bowtie2 (Langmead and Salzberg, 2012) to the mm10 genome and fully

669 processed using the HiC-Pro pipeline (version 2.11.1; Servant et al., 2015) with default parameters. All

670 biological replicates were processed individually to assess their quality and then combined for

671 downstream analyses and visualization. The HiChIP datasets were additionally processed by FitHiChIP

672 (Bhattacharyya et al., 2019). Unless stated otherwise, the following parameters were used to call HiChIP

673 loops: 5,000 kbp resolution, 20000-2000000 distance threshold, FDR 0.01, coverage specific bias

674 correction, merged nearby peak to all interactions. Differential interacting areas between SATB1 and

675 CTCF HiChIP matrices at 100 kbp and 500 kbp resolution were analyzed using diffHic (Lun and Smyth,

676 2015).

677   For the differential analysis of H3K27ac WT and *Satb1* cKO HiChIP datasets, we utilized the

678 differential analysis pipeline from FitHiChIP (Bhattacharyya et al., 2019) and only utilized loops that

679 were classified as differential in 3D but not in 1D. These were loops that showed differences in interaction

680 counts but no significant differences in H3K27ac occupancy at loop anchors. Since some regions

681 contained H3K27ac loops from both under- and over-interacting categories, we furthermore calculated a

682 difference between the number of under- and overinteracting loops.

683   Binding site datasets, needed to call HiChIP loops, were either derived from HiChIP data or an

684 external ChIP-seq dataset. The SATB1 binding sites were extracted from another HiChIP experiment

685 with >60% Dangling End Pairs (~280 million reads), using the PeakInferHiChIP.sh script from

686 FitHiChIP (--nomodel --extsize 147; filter peaks with >2.5 enrichment). SATB1 binding sites were

687 compared to a published SATB1 ChIP-seq dataset (GSM1617950; Hao et al., 2015). Both our biological

688 replicates and the published dataset revealed similar overrepresented categories in genome and gene

689 ontology functional analyses as well as a high overlap of peaks and differentially expressed genes. The

690 H3K27ac peaks were derived similarly from the HiChIP datasets (separately for two biological replicates

691 and then merged). The CTCF peaks were also derived the same way and motif analysis with MEME

692 (Bailey and Elkan, 1994) validated the high enrichment of the CTCF binding motif in the HiChIP derived

30

693   peaks, confirming its specificity. However, due to a relatively low number of HiChIP-derived CTCF

694   binding sites, for FitHiChIP loop calling and other computational analyses, we employed a CTCF ChIP-

695   seq dataset from the ENCODE project (ENCFF714WDP; Dunham et al., 2012). Only for the

696   visualization purposes, we used combined datasets (mergeBed command of bedtools; Quinlan and Hall,

697   2010) of our HiChIP-derived binding sites and publicly available ChIP-seq datasets for both SATB1

698   (GSM1617950; Hao et al., 2015) and CTCF (ENCFF714WDP; Dunham et al., 2012). Since our

699   antibodies were specific for the long SATB1 isoform, we used the dataset combined with the public

700   ChIP-seq to ensure that all types of SATB1 peaks were shown.

701   At the TCR locus, whole DNA segments are missing in some cells due to V(D)J recombination.

702   Thus, in the cell population some regions of TCR are underrepresented compared to other genomic loci

703   and this fact penalizes loop or binding site calling at the TCR locus. For this reason, for the TCR analysis

704   we used different datasets with adjusted and more relaxed parameters to compensate for this. For the

705   purpose of loop calling in HiChIP experiments, we utilized the combined binding site datasets of our

706   HiChIP-derived binding sites and publicly available ChIP-seq datasets for both SATB1 (GSM1617950;

707   Hao et al., 2015) and CTCF (ENCFF714WDP; Dunham et al., 2012). Furthermore, the following

708   parameters were used: 10,000 kbp resolution, 20000-2000000 distance threshold, FDR 0.05, coverage

709   specific bias correction, merged nearby peak to all interactions.

710   For operations with matrices, the datasets were processed using hicexplorer (Ramírez et al.,

711   2018). Hi-C and HiChIP matrices were normalized to the smallest dataset from each compared pair, i.e.

712   WT vs SKO Hi-C, SATB1 vs CTCF HiChIP and WT vs SKO H3K27ac HiChIP. Normalized matrices

713   were corrected using *hicCorrectMatrix* based on the diagnostic plots applying a KR balancing method

714   (Knight and Ruiz, 2013). The analysis of A/B compartments was done according to the original protocol

715   (Lieberman-Aiden et al., 2009) using hicexplorer (Ramírez et al., 2018) and/or by HOMER (Heinz et al.,

716   2010). Differential analysis of TADs was performed using TADCompare (Cresswell and Dozmorov,

717   2020) at 100 kbp resolution on matrices combined for both biological replicates to compare WT and

718   *Satb1* cKO. As a control we also compared TADs called from individual replicates of each genotype.

719   Visualization of matrices was done by hicexplorer (Ramírez et al., 2018), pyGenomeTracks and/or by

720   Juicebox (Durand et al., 2016). APA scores (Rao et al., 2014) were calculated and visualized by SIPMeta

721   (Rowley et al., 2020) and/or by Juicer Tools (Durand et al., 2016).

722   **Stranded-total-RNA sequencing**

723   <u>Experimental protocol</u>

724   Freshly isolated thymocytes from female animals were resuspended in 1 ml of TRIzol Reagent

725   (Invitrogen, 15596026) and RNA was isolated according to manufacturer's protocol. The aqueous phase

726   with RNA was transferred into a tube and combined with 10 μg of Linear Acrylamide (Ambion,

727   AM9520), 1/10 of sample volume of 3M CH3COONa (pH 5.2), 2.5 volumes of 100% Ethanol and tubes

728   were mixed by flipping. Samples were incubated at –80°C for 40 minutes. Samples were centrifuged at

729   16,000 g, at 4°C for 30 minutes. The supernatant was removed and the pellet was washed twice with

730   75% Ethanol. The air-dried pellets were resuspended in 40 μl RNase-free water and incubated at 55°C

731   for 15 minutes to dissolve RNA. To remove any residual DNA contamination, RNase-free DNase Buffer

732   was added to the samples until 1X final concentration together with 20 units of DNase I (NEB, M0303L)

733   and incubated at 37°C for 20 minutes. Samples were then purified using RNeasy Mini Kit (Qiagen,

734   74104) according to the manufacture's protocol. RNA quality was evaluated using Agilent 2100

735   Bioanalyzer with Agilent RNA 6000 Nano Kit (Agilent Technologies, 5067-1511). Libraries were

736   prepared using an Illumina® TruSeq® Stranded Total RNA kit with ribosomal depletion by Ribo-Zero

737   Gold solution from Illumina® according to the manufacturer's protocol and sequenced on an Illumina®

738   HiSeq 4000 (2x 75 bp).

739   <u>Data processing</u>

740   Raw reads were mapped to the mm10 mouse genome using HISAT2 (Kim et al., 2019). Only mapped,

741   paired reads with a map quality >20 were retained. Transcripts were assembled with StringTie (Pertea et

742   al., 2015) using an evidence-based Ensembl-Havana annotation file. Transcripts and genes were

743   summarized using featureCounts (Liao et al., 2014) and statistically evaluated for differential expression

744   using DESeq2 (Love et al., 2014). When application required an intra-sample transcript comparison,

745   DESeq2 values were further normalized to the gene length. The functional analyses were performed by

746   g:Profiler (Reimand et al., 2007). The plots depicting enriched BP terms and KEGG pathways were

747   generated by presenting the top 20 pathways/terms with the lowest p-values.

748   **ATAC-seq**

749   <u>Experimental protocol</u>

750   A biological triplicate was used for each genotype. The ATAC-seq experiment was performed according

751   to the Omni-ATAC protocol previously published (Corces et al., 2017), with modifications. Murine

752   thymocytes were isolated as previously described, without fixation. To ensure the presence of only viable

753   cells, cells were separated using Lympholyte®-M (Cedarlane, CL5030) according to the manufacturer's

754   protocol. Isolated cells were washed twice with 1X PBS and aliquots of 10,000 cells were used for

755   analysis. The cell pellet was gently resuspended by pipetting up and down three times in 50 µl of ice cold

756   ATAC-RSB-NTD Buffer (10 mM Tris-HCl – pH 7.5, 10 mM NaCl, 3 mM $MgCl_2$, 0.1% NP40, 0.1%

757   Tween-20, 0.01% Digitonin) and incubated on ice for 3 minutes. Cell lysis was stopped by adding 1 ml

758   of cold ATAC-RSB-T Buffer (10 mM Tris-HCl – pH 7.5, 10 mM NaCl, 3 mM $MgCl_2$, 0.1% Tween-20)

759   and inverting the tube three times to mix. Nuclei were centrifuged at 1,000 g, at 4°C for 10 minutes. The

760   pellet was resuspended in 50 µl of Transposition Mix [25 µl 2X TD buffer (20 mM Tris-HCl – pH 7.6,

761   10 mM MgCl2, 20% Dimethyl Formamide – before adding DMF, the pH was adjusted to 7.6 with 100%

762   acetic acid), 2.5 µl transposase (100 nM final), 16.5 µl PBS, 0.5 µl 1% digitonin, 1 µl 5% Tween-20, 4.5

763   µl H2O] by pipetting up and down six times. The reaction was incubated at 37°C for 30 minutes with

764   occasional pipetting. DNA was purified with a DNA Clean & Concentrator-5 Kit (Zymo Research,

765   D4013) according to the manufacturer's protocol. DNA was eluted in 20 µl of Elution Buffer and all the

766   material was used in a PCR reaction, together with 25 µl Phusion HF 2X Master Mix (NEB, M0531L)

767   and 2.5 µl of each Nextera Index 1 (N7XX) and Nextera Index 2 (N5XX) primers from a Nextera DNA

768   Sample Preparation Index Kit (Illumina, FC-121-1011). PCR was performed according to the following

769   protocol: 72°C for 5 minutes, 98°C for 1 minute and 5 cycles of 98 °C for 15 seconds, 63 °C for 35

770   seconds, 72 $^\circ$C for 1 minute. The samples were put on ice and 5 µl of the pre-amplified mixture was

771   combined with 15 µl of qPCR Master Mix using the following set-up: water 3.25 µl, primer ad1 0.5 µl,

772   primer ad2 0.5 µl, 20x SYBR Green 0.75 µl, Phusion HF 2x Master mix 5 µl and pre-amplified sample

773   5 µl. The qPCR reaction was run for 20 additional cycles following the program 98°C for 1 minute and

774   5 cycles of 98°C for 15 seconds, 63 $^\circ$C for 35 seconds, 72 $^\circ$C for 1 minute.

775   Based on the Rn (Fluorescence) vs Cycle linear plot, a cycle with 1/4 up to 1/3 of the maximum

776   fluorescence level was determined. This was the number of additional PCR cycles to run on the pre-

777   amplified libraries which were stored on ice until this point. The final amplified libraries were purified

778   using a DNA Clean & Concentrator-5 Kit (Zymo Research, D4013) according to the manufacturer's

779   protocol and eluted in 20 µl of Elution Buffer. Libraries were quantified by Qubit and analyzed on a

780   Bioanalyzer as previously described, followed by two-sided size selection using AMPure Beads.

781   Libraries were sequenced on an Illumina® HiSeq 4000 2x 75 bp platform by the sequencing facility at

782   IKMB, Kiel University, Germany.

783   <u>Data processing</u>

784   To acquire BAM files and ATAC-seq peaks, raw data were fully processed by the esATAC pipeline

785   (Wei et al., 2018). To identify the regions with differential accessibility between genotypes, all esATAC

786   called peaks across samples and replicates were pooled and tested for differences in accessibility levels.

787   ATAC-seq counts were calculated for each peak, each replicate and each condition using FeatureCounts

788   (Liao et al., 2014) and used as an input for edgeR (Robinson et al., 2010) with the standard parameters.

789   A cutoff of |logFC|≥1 and p-value ≤0.01 was used to determine the differentially accessible regions.

790   To assess the accessibility around SATB1 binding sites BigWig files were generated.

791   Mitochondrial reads and PCR duplicates were removed from all bam files using samtools (Li et al., 2009)

792   and Picard MarkDuplicates (http://broadinstitute.github.io/picard/), respectively. Low quality and

793   unmapped reads were removed using the following samtools command: samtools view h -b -F 1804 -f 2

794   -q 30. The final bam files were merged for the two conditions using samtools and RPKM normalized

795   BigWig files were generated using deeptools (Ramírez et al., 2016) with the following parameters: -of

796   bigwig   --effectiveGenomeSize   2652783500   --normalizeUsing   RPKM   -bl

797   New_merged_mm10.blacklist.bed -bs 1. mm10 blacklisted regions were downloaded from ENCODE.

798   Moreover, using the merged bam files, BigWig files with the log2 ratio between the normalized reads of

799   *Satb1* cKO and WT thymocytes were generated using deeptools bamCompare. The parameters were the

800   same as above. SATB1 binding sites were first centered and then extended by 250 bp upstream and

801   downstream. For each bp position, ATAC-seq signal was calculated using the generated BigWig files.

802   Similarly, each TSS of each gene was centered and extended by 1 kbp upstream and downstream. For

803   each base of each gene, an average log2 fold change of normalized accessibility score (*Satb1* cKO vs

804   WT) was plotted. To calculate the accessibility changes along the entire genes, genes and upstream and

805   downstream regions were divided into bins and average log2 fold change of normalized accessibility

806   score for each bin was plotted.

807   **Immunofluorescence experiments**

808   Glass coverslips were coated by dipping in 0.1 mg/ml poly-D-lysine solution (Sigma Aldrich, P6407).

809   Freshly isolated thymocytes were attached to the coated coverslips. Attached cells were washed once

810   with 1X PBS and then fixed for 10 minutes on ice with 4% formaldehyde (Pierce, 28908) in 1X PBS.

811   Fixed cells were permeabilized with 0.5% Triton-X in 1X PBS for 5 minutes on ice. Cells were washed

812   three times with 1X PBS for 5 minutes each and blocked for 30 minutes at RT with Blocking Buffer

813   [0.4% acetylated BSA (Ambion, AM2614) in 4X SSC] in a humidified chamber. Cells were incubated

814   for 1.5 hours at RT with an antibody against Hp1α (Merck Millipore, MAB3584, 1:500 dilution) and

815   RNA Polymerase II (Santa Cruz, sc-900, 1:50) in Detection Buffer (0.1% acetylated BSA, 4X SSC, 0.1%

816   Tween 20) in a humidified chamber. The excess of antibodies was washed away by three washes for 5

817   minutes each with Washing Buffer (4X SSC, 0.1% Tween 20). Cells were incubated for 60 minutes at

818   RT with a goat anti-rabbit antibody conjugated with Alexa Fluor 488 (1:250) and a goat anti-mouse

819   antibody conjugated with Alexa Fluor 647 (1:250) in Detection Buffer (0.1% acetylated BSA, 4X SSC,

820   0.1% Tween 20) in a humidified chamber. The excess was washed away by three washes for 5 minutes

821   each with Washing Buffer (4X SSC, 0.1% Tween 20). The cells were mounted in a hardening ProLong

822   Gold medium with DAPI (Invitrogen, P36935). Images were taken using an inverted microscope

823   DMI6000 CS with laser scanning confocal head Leica TCS SP8, equipped with a 63x/1.40 oil immersion

824   objective. Images were analyzed using the Fiji software (Schindelin et al., 2012). Cells were manually

825   selected and signal was measured as an integrated signal density from summed z-stacks.

Cultivation of neonatal thymi

826

827   Thymi of neonatal WT and *Satb1* cKO mice were collected and embedded in collagen. Thymi were

828   cultivated in a medium (10% FBS, RPMI, Hepes, Pen-Strep, Glutamine, β-mercaptoethanol) for 30 hours

829   and monitored with the Operetta high content screening microscope (PerkinElmer) to detect cells exiting

830   the thymus. Images were pre-processed with the in-built analysis software Harmony 4.1 and then

831   analyzed with custom-made macros in Fiji software (Schindelin et al., 2012). Random shifts were

832   corrected by a StackReg plugin (Rigid Body transformation). Areas without any distortion were selected

833   and cells outside the thymus were counted using Find Maxima function of Fiji. Each selection was

834   normalized to the area size and for each animal the selections were averaged. The final result represents

835   an average from different animals for each genotype.

Linear regression model

836

837   A linear regression model was built in R and used to identify the impact of individual variables from our

838   datasets on log2FC RNA-seq values. The predictors used are described below: Each gene was binned

839   into 3 bins. Moreover, two extra bins upstream of the TSS of each gene (upstream region: –4 kbp to –2

840   kbp and promoter region: -2kb to TSS) and two extra bins downstream of the transcription termination

841   site (TTS to +2 kbp and +2 kbp to +4 kbp) were used. SATB1 binding occupancy in WT cells was

842   determined via a binary score for each bin of each gene. "1" indicated the presence of a SATB1 peak and

843   "0" the absence of a SATB1 peak overlapping with the corresponding bin.

36

844   To quantify ATAC-seq signal differences between the *Satb1* cKO and WT thymocyte samples,

845   the following calculation for each bin of each gene was used: log10[(*Satb1* cKO Normalized Reads +

846   0.01) / (WT Normalized Reads + 0.01)] * log2(Total Normalized Reads + 1)

847   To utilize SATB1 and CTCF loops as predictors, we assigned to each gene the number of times

848   it overlapped with the anchors of a SATB1 or CTCF loop. In case that both anchors of the same

849   SATB1/CTCF loop overlapped a gene, only one was counted. The number of times, the anchors of a

850   SATB1 loop were found to connect an enhancer with a gene, was also used as a predictor. The same

851   metrics were calculated for overinteracting and underinteracting H3K27ac loops.

852   The quality plots of the model are depicted in Figure S2A-D and the adjusted R-square of the

853   model was 0.1128. The change of the Akaike Information Criterion (AIC, Figure S2E) estimated how

854   the quality of the model was affected when all the predictors were kept intact except one. The y-axis

855   corresponds to the removed predictor, while the x-axis indicates how the AIC for the new model was

856   altered. An increase indicated that the predictor was "useful" for the model. Based on the AIC plot,

857   neither SATB1 binding upstream and downstream of genes nor CTCF-mediated loops contributed to the

858   accuracy of the model. On the other hand, differences in chromatin accessibility and connectivity via

859   H3K27ac loops along with SATB1-mediated loops performed very well as predictors. Non-useful

860   predictors were not used in the final model. The final model coefficients for the important predictors are

861   displayed in Figure S2F. The sign of each coefficient indicates whether a predictor is associated with

862   decreased (negative) or increased (positive) RNA levels in *Satb1* cKO. Genes present at anchors of

863   overinteracting H3K27ac chromatin loops and/or with increased chromatin accessibility were associated

864   with increased RNA levels in *Satb1* cKO. In contrast, the genes present at anchors of underinteracting

865   H3K27ac chromatin loops or SATB1-mediated loops and/or genes bound by SATB1 were associated

866   with reduced RNA levels.

867   **Additional bioinformatics analyses**

868   Identification of SATB1 binding in H3K27ac HiChIP anchors

37

869   Loop anchors from WT H3K27ac HiChIP loops were pre-processed by extracting the anchors from both

870   sides of loops and then they were merged into non-overlapping unique regions (mergeBed command of

871   bedtools; Quinlan and Hall, 2010). The resulting regions were converted from mm10 to mm9 using

872   CrossMap (Zhao et al., 2014) and were analyzed using the enrichment analysis ChIP-Atlas (Oki et al.,

873   2018) against all the available murine ChIP-seq datasets from the blood cell type class and compared to

874   100X random permutations.

875   Publicly available ChIP-seq datasets

876   We utilized the CTCF ChIP-seq dataset from the ENCODE project (ENCFF714WDP; Dunham et al.,

877   2012) and the SATB1 ChIP-seq (GSM1617950; Hao et al., 2015). For the analysis of enhancers, in

878   relation to SATB1 and CTCF loops, we utilized the thymus-specific list of enhancers previously

879   generated within the ENCODE project (GSE29184; Shen et al., 2012) – after extending the center of

880   each enhancer by 50 bp upstream and downstream. Moreover, for visualization purposes we also utilized

881   the H3K4me3 (ENCFF200ISF) and H3K4me1 (ENCFF085AXD) ChIP-seq datasets for thymus, from

882   the ENCODE project (Davis et al., 2018). The H3K27ac ChIP-seq datasets were from WT and

883    $Rad21^{fl/fl}Cd4$-Cre$^+$ DP cells (Ing-Simmons et al., 2015) and they were first converted from mm9 to mm10

884   using CrossMap (Zhao et al., 2014). An average file based on two biological replicates (GSM1504384+5

885   for WT and GSM1504386+7 for $Rad21$ cKO) was created and used for visualization.

886   Overlap score calculation for HiCHIP loops

887   The overlap score between SATB1 and CTCF loops was calculated as (number of overlapping bp) / (bp

888   size of a loop). Overlaps between the two types of loops were found using bedtools (Quinlan and Hall,

889   2010) and the above score was calculated using R. A score of one indicates either 100% overlap or

890   engulfment of a loop mediated by one factor in a loop mediated by another factor. A score of zero

891   indicates no overlap. In cases where a loop mediated by one factor intersected with multiple loops

892   mediated by the other factor, the maximum score was used.

893   Functional analyses of gene lists

894   All gene ontology pathway analyses were performed with the R package gProfileR (Reimand et al.,

895   2007). Twenty biological processes pathways with the lowest p-values were plotted.

Nucleosome binding

897   Nucleosome positions and factor occupancy was analyzed with NucleoATAC (Schep et al., 2015).

898   NucleoATAC was run with standard parameters on merged ATAC-seq bam files, separately for each

899   genotype. SATB1 and CTCF binding sites were used as the input for the occupancy analysis. Peaks were

900   centered and extended 250 bp upstream and downstream prior to the analysis.

Transcriptional insulation scores

902   We investigated whether the expression of genes inside SATB1 and CTCF loops was different from the

903   neighboring genes outside the loops. To test this, we established an insulation score by calculating the

904   difference between the mean expression of genes inside loops [log10(counts / gene length + 0.01)] and

905   the mean expression of genes found in the same size regions upstream and downstream from each loop.

906   To compare the isolated values against a null distribution, loop coordinates were randomly shuffled

907   across the genome and differences between the expression of genes residing inside the randomized loops

908   with their neighbors were calculated as described above. If a shuffled loop was not containing any genes

909   it was re-shuffled.

Permutation analyses

911   In order to construct a null statistical model (e.g. determination of common genes between two gene

912   subsets, estimation of expected peak overlaps), permutation analyses were performed. In cases of

913   overlaps between two files with genomic coordinates, the coordinates of one file were shuffled 1,000

914   times with the bedtools shuffle command (Quinlan and Hall, 2010). The new overlap for each iteration

915   was calculated. The mean overlap count was used to determine enrichment. Finally, a p-value was

916   calculated as follows: p-value = (X times the permutation overlap was higher than the actual overlap /

917   1000). The same was applied for overlaps between gene lists, with the exception of drawing out random

918   genes instead of shuffling coordinates.

39

919   To generally test a null hypothesis for randomly selected values X and Y from two populations,

920   the probability of X being greater than Y is equal to the probability of Y being greater than X, we used a

921   nonparametric Wilcoxon rank sum test (ggsignif R package).

922   To statistically evaluate accessibility of SATB1 peaks (Figure 3B), each SATB1 HiChIP peak

923   was centered and extended 250 bp upstream and downstream. An average read-depth normalized ATAC-

924   seq score was calculated for each centered peak using the UCSC executable, bigWigSummary. Scores

925   were log10 transformed. The process was repeated 100 times after random shuffling of the centered and

926   extended peaks across the mm10 genome. The shuffleBed command from the bedtools suite (Quinlan

927   and Hall, 2010) was used to shuffle the peaks. The average accessibility scores were calculated for the

928   permuted and the "real" value distributions. A bootstrap p-value was calculated as: Number of randomly

929   permuted mean values bigger than the "real" mean value / 100. In order to identify SATB1 peaks that

930   occupied regions with reduced accessibility levels (Figure S1K), the aforementioned analysis was

931   performed with 10 permutations. The average log10 transformed read-normalized accessibility scores of

932   the ten random permutations was used as a cutoff for picking SATB1 peaks with low accessibility levels.

933   <u>3D computational modeling</u>

934   The WT and *Satb1* cKO thymocyte Hi-C contact matrices, binned at a resolution of 20 kbp, were pre-

935   processed by vanilla coverage normalization (Rao et al., 2014). An area delimited by two TADs (called

936   by hicexplorer; Ramírez et al., 2018) at 150 kbp resolution and spanning chr16: 21420000-25340000)

937   encompassing the *Bcl6* locus (chr16: 23965052-23988612) was used for 3D modeling of chromatin

938   interactions, using TADbit Python library (Serra et al., 2017). Each contact matrix was modeled as a

939   coarse-grained "beads-on-a-string" polymer model at an equilibrium scale of 0.01 nm/bp. First, we

940   identified the optimal parameters to establish Z-score thresholds for attractive (*upfreq*) and repulsive

941   (*lowfreq*) restraints, maximum inter-locus distance (*maxdist*) and maximum model physical distance,

942   below which two model loci could be considered in contact with each other. Out of 500 models in total,

943   we selected 100 models with the lowest amount of violated contact restraints. Next, we generated an

944   ensemble based on the selected 100 models. Parameters were selected using a grid search approach aimed

945   to optimize the correlation between the experimental input and the ensemble, as a model-derived contact

946   map. The selected parameters were for WT: upfreq –0.3, lowfreq –1.0, maxdist: 550, cutoff dist: 400.0

947   and for *Satb1* cKO: upfreq 0.0, lowfreq –2.0, maxdist: 1100, cutoff dist: 800.0. We used the optimized

948   set of parameters and based on correlation between the model and the experimental contact maps, we

949   selected the top 5,000 models (out of 25,000 models) to generate a production ensemble. Production

950   ensembles were well correlated with the input Hi-C contact matrices (Spearman's r = 0.716 for WT and

951   r = 0.7877 for *Satb1* cKO).

952   The production ensemble models were clustered using TADbit's built-in objective function and

953   the MCL Markov clustering (Enright et al., 2002). The centroid model of the first cluster for each

954   genotype was visualized using the UCSF Chimera molecular visualization software (Pettersen et al.,

955   2004) at a scale of 1:4. The models were colored according to the distance from the 5'-end. The

956   highlighted beads represent an approximation of SATB1 loop anchors derived from SATB1 HiChIP data

957   at *Bcl6* (yellow) and its super-enhancers (black). The WT models were rotated to obtain a clear view of

958   all relevant structures and then aligned to the *Satb1* cKO-derived models using the match command.

959   The three-dimensional structures in the production ensemble were used to calculate the distance

960   distribution between the beads corresponding to the loci closest to the *Bcl6* locus and its proximal super-

961   enhancer 1 (corresponding to chr16:23980000-24000000 and chr16:24240000-24260000, respectively).

962   The resulting distributions of the WT and *Satb1* cKO data were compared using the Mann-Whitney U

963   test and assessed for multimodality with the skinny-dip test (Maurus and Plant, 2016). The distances

964   between *Bcl6* and its super-enhancer based on the ensemble of the 5,000 sampled models were: mean

965   rank WT: 2616.3162; mean rank *Satb1* cKO: 7384.6838 (p = 0.0; Mann-Whitney U test). Dip test results

966   (distribution modes): WT: [171.205, 200.087], [200.248, 298.606] (p < 0.001); *Satb1* cKO: [198.063,

967   441.868].

Figure legends

Figure 1. Autoimmune-like phenotype of the Satb1 cKO mouse

(A) Anchors of regulatory H3K27ac HiChIP loops in murine WT thymocytes are enriched for the ChIP-seq peaks of the factors depicted in the table. The analysis was based on the ChIP-Atlas (Oki et al., 2018), thus the datasets and underlying study ID match SRA databases.

(B) Distribution of fold-enrichment of all available ChIP-seq datasets based on ChIP-Atlas (Oki et al., 2018) at WT H3K27ac loop anchors over random permutation and the corresponding p values. All available SATB1 ChIP-seq datasets (highlighted in red) evinced enrichment at the anchors of regulatory chromatin loops.

(C) Flow cytometry in cell populations of the thymus and the spleen for the expression of CD4 and CD8 cell surface markers as well as CD62L (naiveness marker) and CD44 (lymphocyte activation marker). Used animals were divided into young (45±11 days; 6 WT, 6 Satb1 cKO) and old (179±35 days; 7 WT, 9 *Satb1* cKO) age categories. Only young animals were used for analysis of thymus due to its deterioration in old animals. Three young animals for each genotype were used for CD62 / CD44 analysis.

(D) Differences in the cytokine milieu in the blood serum of WT and *Satb1* cKO animals measured with bead-based immunoassay, point to an elevated Th17 response and increased inflammatory cytokines.

(E) *Satb1* cKO animals display an autoimmune-like phenotype. T cells infiltrated peripheral organs, including pancreas, which resulted into damaged islets of Langerhans and consequently impaired glucose metabolism. BF indicates steady-state glucose levels, before 6 hour fasting period.

(F) WT pancreas sections were incubated with serum from either WT or *Satb1* cKO animals to detect the presence of autoantibodies. Scale bar in all images is 100 μm.

In (C, D and E) if present, the horizontal lines inside violins represent the 25th, 50th and 75th percentiles. Red circle represents mean ± s.d. *P* values by Wilcoxon rank sum test. In (D and E), SKO represents *Satb1*$^{fl/fl}$*Cd4*-Cre$^+$ animals.

51

Figure 2. T cell chromatin organization mediated by SATB1 and CTCF

(A) Comparison of WT and *Satb1* cKO Hi-C heatmaps of chromosome 11 indicates no major changes at high order chromatin level in murine thymocytes.

(B) diffHic analysis (Lun and Smyth, 2015) of differentially interacting chromatin areas indicates that CTCF contributes more strongly to the higher order chromatin organization of the murine T cell genome than SATB1.

(C) SATB1-mediated loops highly intersect with CTCF-mediated loops detected by HiChIP. For the intersection, the outer coordinates of left and right loop anchors were used.

(D) Overlap score between SATB1 and CTCF loops calculated as (number of overlapping bp) / (bp size of a loop). For example, for the SATB1-labeled violin, a score of 1.0 indicates either 100% overlap or engulfment of a SATB1-mediated loop in a loop mediated by CTCF. A score of 0.0 indicates no overlap. The plot indicates that the majority of the SATB1 loops were engulfed in CTCF loops. The same approach was repeated for randomly shuffled loops. *P* values by Wilcoxon rank sum test.

(E) SATB1 preferentially binds nucleosomes unlike CTCF.

(F) SATB1 loop anchors overlap with genes enriched for immune system-related categories. CTCF-mediated loops display more widespread coverage of intersecting genes thus the most enriched gene ontology pathways belong mostly to general cellular processes.

Figure 3. SATB1-mediated chromatin loops positively regulate gene expression

(A) Immunofluorescence analysis with confocal microscopy of WT and *Satb1* cKO thymocytes stained with antibodies against HP1α and RNA Pol II. The nuclei of *Satb1* cKO thymocytes had stronger HP1α signal, suggesting a more repressed nuclear environment. The values in the graph represent an integrated signal density from summed z-stacks. SKO represents *Satb1*^{fl/fl}*Cd4*-Cre⁺ animals. The horizontal lines inside violins represent the 25th, 50th and 75th percentiles. The red circle represents the mean ± s.d. *P* values by Wilcoxon rank sum test. Scale bar 5 μm.

1342 (B) ATAC-seq signal indicates higher chromatin accessibility at WT SATB1 binding sites than expected

1343 by chance (i.e, randomly shuffled SATB1 binding sites). 100 randomizations were used to for statistical

1344 evaluation (bootstrap p-value = 0). Two representative random distributions are depicted in the figure.

1345 (C) Chromatin accessibility at SATB1 binding sites is decreased in *Satb1* cKO.

1346 (D) Log2 fold change of chromatin accessibility indicates the highest accessibility drop in *Satb1* cKO

1347 being at the TSS of genes.

1348 (E) Inference tree systematically probing all options of SATB1 binding and looping as well as their

1349 impact on gene expression. The x-axis indicates the ranges of log2 fold change RNA-seq values. For

1350 example, 5% of the most underexpressed genes in *Satb1* cKO represent ~20% of genes (y-axis) found in

1351 anchors of SATB1-mediated loops connected to an enhancer (first red arrow). The red arrows highlight

1352 the disruption of the normal distribution of differentially expressed genes in the respective ranges that is

1353 present in SATB1-mediated loops. Differentially expressed genes that do not overlap with anchors of

1354 SATB1 loops display a normal distribution – reflecting the respective log2 fold change ranges (the three

1355 rightmost graphs).

1356 (F) SATB1-mediated loops connecting genes to enhancers are about three-fold enriched compared to

1357 CTCF loops.

1358 (G) SATB1-mediated loops connected to enhancers evince enriched interaction signal between left and

1359 right anchor in WT Hi-C data, which is deregulated in *Satb1* cKO. Aggregate peak analysis (APA; Rao

1360 et al., 2014) was calculated and visualized by SIPMeta (Rowley et al., 2020).

1361 **Figure 4. SATB1 mediates promoter-enhancer communication of critical immune-related genes**

1362 (A) Positive correlation (Spearman's ρ = 0.26) between gene expression changes and the difference

1363 between H3K27ac overinteracting and underinteracting loops in WT thymocytes compared to *Satb1*

1364 cKO. Negative values on the x-axis represent prevailing H3K27ac loops that were lost or diminished in

1365 *Satb1* cKO, whereas positive numbers refer to gained H3K27ac loops in the knockout.

1366   (B) Log2 fold change expression values of genes that were present in anchors of H3K27ac HiChIP loops

1367   underinteracting in *Satb1* cKO and which also did or did not intersect with SATB1/CTCF-mediated

1368   loops. An equal number of underinteracting loops that did not overlap with SATB1/CTCF-mediated

1369   loops were randomly generated. *P* values by Wilcoxon rank sum test.

1370   (C) The same as in (B) visualized for H3K27ac HiChIP loops overinteracting in *Satb1* cKO.

1371   (D) The *Bcl6* gene is connected by two SATB1 loops to its super-enhancer regions. Figure depicts the

1372   shorter SATB1 loop connecting *Bcl6* (same loop anchor for both loops; chr16:23985000-23990000) with

1373   the more proximal super-enhancer region 1 (SE1; chr16:24245000-24250000) and a part of the larger

1374   SATB1 loop (chr16:24505000-24510000). In *Satb1* cKO, these interactions were lost as seen in the Hi-

1375   C data analysis (heatmap in the top). Legend: th – thymocytes, DP – CD4$^+$CD8$^+$ T cells, RKO –

1376   *Rad21*$^{fl/fl}$*Cd4*-Cre$^+$ and SKO – *Satb1*$^{fl/fl}$*Cd4*-Cre$^+$.

1377   (E) Computational 3D modeling utilizing the WT Hi-C and *Satb1* cKO Hi-C data, to visualize the

1378   proximity between the *Bcl6* gene body and its two super-enhancer regions / SATB1 loop anchors. The

1379   black beads represent the edge of super-enhancer regions demarcated by the SATB1 loop anchors [SE1

1380   and the short loop are also depicted in (D)]. Color gradient represents linear genomic position along the

1381   locus.

1382   (F) Hematoxylin-Eosin staining of WT and *Satb1* cKO spleen sections revealed disturbed germinal

1383   centers in the knockout.

1384   **Figure 5. TCRα gene locus chromatin organization depends on SATB1**

1385   (A) Genomic tracks as well as SATB1 and CTCF HiChIP loops at the T cell receptor alpha locus (TCRα).

1386   The bottom green genomic tracks of log2 fold change RNA-seq values summarize the overall

1387   deregulation of the TCRα locus, with variable regions (*Trav* genes) being mostly underexpressed, TCRδ

1388   locus overexpressed and TCRα joining regions (*Traj* genes) displaying geometrically symmetric

1389   deregulation splitting the region into over- and under-expressed in *Satb1* cKO cells (magenta arrow).

1390   This deregulation was markedly correlated with the presence of SATB1-mediated loops. Note especially

1391 the region of joining genes which manifests a deregulation similar to previous reports from *Satb1*

1392 depleted animals (Feng et al., 2021; Hao et al., 2015). Both SATB1 and CTCF loops displayed a tendency

1393 to connect the TCR enhancer (green arrow) to the regions inside the locus. The presented loops were

1394 called with low stringency parameters and with a different set of binding sites compared to the rest of

1395 our study due to technical details explained in the methods section.

1396 (B) SATB1 mediates promoter-enhancer regulatory loops controlling the expression of both *Rag1* and

1397 *Rag2* genes.

1398 (C) RNA levels of *Rag1* and *Rag2* genes in WT and *Satb1* cKO thymocytes.

1399 (D) Protein levels of RAG1 (1:2500, Abcam ab172637) and RAG2 (1:100, Santa Cruz Biotechnology

1400 sc-517209) were just marginally affected in the *Satb1* cKO thymocytes (beta Actin as a loading control;

1401 1:500, ORIGENE TA811000).

1402 (E) Differential H3K27ac HiChIP loops reflected the deregulation of *Traj* regions.

1403 In (A, B and D), H3K27ac datasets originate from CD4$^+$CD8$^+$ T cells, all the other datasets from

1404 thymocytes. RKO denotes *Rad21*$^{fl/fl}$*Cd4*-Cre$^+$ and SKO – *Satb1*$^{fl/fl}$*Cd4*-Cre$^+$.

1405 **Figure 6. Deregulated expression of genes encoding adhesion molecules and receptors in the Satb1**
1406 **cKO thymocytes**

1407 (A) Pathway analysis for the genes differentially expressed in the *Satb1* cKO compared to WT

1408 thymocytes as deduced by RNA-seq. Biological adhesion was the top gene ontology pathway in *Satb1*

1409 cKO underexpressed genes.

1410 (B) Important thymic receptors were underexpressed in *Satb1* cKO.

1411 (C) *Cd28* gene regulated via SATB1-mediated promoter-enhancer chromatin loops. There was a SATB1-

1412 mediated regulatory loop and correspondingly increased interactions in the WT Hi-C which were

1413 decreased in the *Satb1* cKO Hi-C. Legend: th – thymocytes, DP – CD4$^+$CD8$^+$ T cells, RKO –

1414 *Rad21*$^{fl/fl}$*Cd4*-Cre$^+$ and SKO – *Satb1*$^{fl/fl}$*Cd4*-Cre$^+$.

1415   (D) Thymic sections displaying a disrupted thymic environment in the *Satb1* cKO. Thymic cryosections

1416   stained with Hematoxylin & Eosin (H&E) and with methylene blue indicated the decreased cellular

1417   density and decreased contacts between cells in the *Satb1* cKO compared to WT thymus. The

1418   transmission electron microscopy images are representative of four biological replicates to underscore

1419   the missing cellular contacts between the *Satb1* cKO cells.

1420   (E) Number of thymocytes in WT and *Satb1* cKO mice. The horizontal lines inside violins represent the

1421   25th, 50th and 75th percentiles. The red circle represents the mean ± s.d. *P* values by Wilcoxon rank sum

1422   test.

1423   (F) The thymus of the *Satb1* cKO animals contained more apoptotic and necrotic cells as deduced by

1424   flow cytometry analysis using Annexin V and propidium iodide staining.

1425   (G) Neonatal thymi from WT and *Satb1* cKO mice were cultivated for 30 hours. An image was taken

1426   every hour to monitor the rate of T cell exit from the thymus. The error bars represent the standard error

1427   of the mean.
