47 **ABSTRACT**

48 Whether the immune response to injury contributes to tissue regeneration is not well
49 understood. We quantified systemic and local cytokines during ear pinna repair to provide the
50 first comprehensive comparison of the immune response to injury between mammalian
51 regeneration (*A. cahirinus* and *A. percivali*) and fibrotic repair (*M. musculus*). Importantly, by
52 comparing laboratory-reared and wild-caught animals we identified responses specifically
53 associated with healing outcome. Fibrotic repair showed a greater local release of IL-6, CCL2
54 and CXCL1. Conversely, regeneration showed decreased circulating IL-5, IL-6, IL-17, CCL3
55 and CXCL1 and increased local IL-12 and IL-17. The differential IL-6 response was
56 substantiated by increased pSTAT3 during the inflammatory phase of fibrotic repair and with
57 blastema formation and tissue morphogenesis in *Acomys*. COX-2 inhibition was not sufficient to
58 induce regeneration. Interestingly, a unique influx of lymphocytes was coupled with
59 regeneration and RNA-expression analysis suggested they were regulatory T cells. Together, the
60 data support regeneration-specific inflammation and T cell responses in *Acomys*.

64 INTRODUCTION

65 Epimorphic regeneration in response to tissue damage occurs as a chronological and
66 overlapping series of processes that includes hemostasis, inflammation, re-epithelialization,
67 activation of local progenitor cells, tissue morphogenesis, and replacement of the injured tissue.
68 The outcome of these processes is scar-free healing. In contrast, most human injuries heal by
69 fibrotic repair, which is characterized by limited cellular proliferation and intense collagen
70 deposition that results in a scar repairing the damaged tissue [1]. As with any trauma or infection
71 that disrupts tissue architecture, regeneration and fibrotic repair are concomitant with a
72 multiphasic immune response that promotes hemostasis, creates inflammation, protects against
73 microbial infection, initiates re-epithelialization, and stimulates a local fibrotic response [2].
74 During most instances of regeneration (e.g., limb, fin, digit tip, etc.) there is an apparent
75 resolution of acute inflammation that coincides with the accumulation of resident cells, which
76 subsequently re-enter the cell cycle and self-organize to undergo morphogenesis [3, 4]. This
77 transition from an inflammatory environment to morphogenesis is synonymous with regenerative
78 blastema formation [5]. As such, the injured tissue must precisely coordinate dynamic
79 interactions between cells and factors (i.e., cytokines, chemokines, growth factors etc.) within the
80 injury microenvironment to resolve the inflammatory response and promote blastema formation.

81 Despite a rich literature describing the effects of immune cells and their products in non-
82 regenerating wounds [6, 7], our knowledge of the immune response during epimorphic
83 regeneration remains poor [8-10]. Recent studies in fish, frogs, salamanders, and spiny mice
84 support that immune cells and their products are required for blastema formation and successful
85 regeneration. For instance, complete or timed depletion of macrophages or regulatory T cells
86 (T_{REG}) prevents re-epithelialization and subsequent blastema formation [11-18] and blocking

87 reactive oxygen species (ROS) production elicits a similar outcome [19-21]. Perhaps not
88 unexpectedly, similar experiments in non-regenerating systems cause incomplete wound closure
89 and angiogenesis, suggesting that the same immune signals initiate fibrotic repair and
90 regeneration [22-27]. Moreover, comparing the immune response to injury between fetal and
91 adult mammals [28-30], pre- and post-metamorphic amphibians [31-33], closely-related
92 regenerating and non-regenerating vertebrates [34], and regeneration-competent and scarring
93 tissues in the same animal [35-37] all support that reduced inflammation and a muted immune
94 response promotes epimorphic regeneration over fibrotic repair. However, an important series of
95 studies support the idea that some immune cells are passive participants during tissue
96 regeneration. For example, removal of the spleen [38], or induction of leukopenia [39] during
97 newt limb regeneration demonstrate that a severely reduced leukocyte response does not prevent
98 blastema formation or regeneration.

99 These contrasting viewpoints raise several unanswered questions. (1) Are there specific
100 factors produced by immune cells that polarize local cell phenotypes and specifically promote
101 regeneration or fibrotic repair? (2) Does the inflammatory response impede blastema formation
102 and subsequent regeneration in adult mammals? (3) Are the initial stages of fibrotic repair and
103 regeneration driven by different immune responses, such that altering the immune response
104 could stimulate regeneration in lieu of fibrotic repair? In order to address these questions and to
105 test how immune cell factors specifically affect resident cells in injured tissue, there is a need to
106 establish the timing and extent to which these factors are deployed during regeneration and
107 fibrotic repair.

108 In this study, we provide insight of the immune mechanisms that coincide with
109 mammalian regeneration by following-up on the relatively recent discovery that multiple species

110 of spiny mice (e.g., *Acomys cahirinus*, *A. percivali*, *A. kempfi*) regenerate skin and
111 musculoskeletal tissue [15, 40-42]. Previous work in spiny mice supports that epimorphic
112 regeneration is associated with resident cell activation, cell cycle progression, cell proliferation,
113 and an inflammatory response distinguished by a prolonged signature of NADPH-oxidase-
114 derived ROS [15, 40, 42]. Additionally, macrophages are required for blastema formation in
115 spiny mice [15], and there is additional evidence that macrophage subtypes differentially drive
116 regeneration or fibrotic repair in rodents [15-17]. Therefore, we sought to characterize and
117 compare the cytokine response to injury during fibrotic repair and regeneration to specifically
118 test if the immediate immune response to injury is different between these two healing outcomes.

119 We compared the injury response using a 4 mm ear punch assay among three species (*A.*
120 *cahirinus*, *A. percivali* and *M. musculus*) and two source populations (wild-caught *A. percivali*
121 and *M. musculus*, and laboratory-reared *A. cahirinus* and *M. musculus*) using a panel of sixteen
122 cytokines. Our results showed that injury across all groups induced a common set of pro-
123 inflammatory cytokines (IL-1 β , IL-6, TNF α) and leukocyte chemotactic factors (GM-CSF/CSF2,
124 and MIP-1 α /CCL3) with a similar timed resolution, supporting that some signals of acute
125 inflammation are a shared feature of regeneration and fibrotic repair. Supporting a difference
126 between regeneration and fibrotic repair, we observed differential responses for several pro-
127 inflammatory cytokines during the acute inflammatory phase. Surprisingly, we found a faster,
128 stronger and prolonged adaptive immune response characterized by T cell influx during
129 regeneration.

130

131 **RESULTS**

132 **Cross-species validation of cytokine detection in rodent serum and tissue**

133 To begin characterizing the mammalian immune response during epimorphic
134 regeneration, we analyzed sixteen cytokines (Interleukin 1-alpha (IL-1 α), IL-1 β , IL-2, IL-4, IL-5,
135 IL-6, IL-10, IL-12p70, IL-17, chemokine (C-C motif) ligand 2 (CCL2) (a.k.a. monocyte
136 chemoattractant protein 1 or MCP-1), CCL3 (a.k.a. macrophage inflammatory protein 1 α or
137 MIP-1 α), CCL5 (a.k.a. regulated on activation, normal T cell expressed and secreted or
138 RANTES), colony-stimulating factor 2 (CSF2) (a.k.a. granulocyte-macrophage colony-
139 stimulatory factor or GM-CSF), tumor necrosis factor-alpha (TNF α), interferon-gamma (IFN γ)
140 and chemokine (C-X-C motif) ligand 1 (CXCL1) (a.k.a. KC)) using a custom-designed sandwich
141 ELISA array. We used this assay to compare five groups: three at the University of Kentucky,
142 (1) laboratory-reared, outbred *Mus musculus* (Mm-UKY), (2) wild-caught *M. musculus* (Mm-
143 Wild), (3) laboratory-reared *Acomys cahirinus* (Ac), and two at the University of Nairobi, (4)
144 outbred *M. musculus* reared by a local breeder (Mm-Kenya) and (5) wild-caught *A. percivali*
145 (Ap). Our experimental design allowed us to compare cytokine responses between regenerating
146 and non-regenerating species (Ac and Ap compared to Mm-UKY, Mm-Kenya and Mm-Wild),
147 and between immune-challenged and laboratory-reared animals (Mm-Kenya, Mm-Wild and Ap
148 compared to Mm-UKY and Ac).

149 Parallelism analysis showed comparable slopes between *Mus* and *Acomys* serum and
150 tissue samples with the mouse standard curve for a majority of cytokines (Table 1 and
151 Supplementary Figure 1). Given non-parallel slopes, we did not validate using this assay to
152 compare IL-10 or CCL5 between species (Figure S1). Several cytokines not present in *Acomys*
153 serum were quantified in tissue lysate (Ac: IL-1 β , IL-4, IL-6, IL-17, CSF2, CCL2; Ap: IL-17,

154 CSF2, CXCL1) supporting that the serum concentration was below the limit of detection and that
155 the antibody binding epitopes were conserved between species. Therefore, if the cytokine was
156 detected in one tissue source or one *Acomys* species, we concluded it could be detected in the
157 other source or species. This provided us with a way to determine if the cytokine was present or
158 absent. A comparison of full-length predicted amino acid sequences between *A. cahirinus* and
159 *M. musculus* indicated conservation—minimum of 56.8% (IFN γ) to a maximum of 95.8%
160 (TNF α) (Table 2 and Supplemental Figure 2A-Q). Given that CXCL1 was the only cytokine not
161 detected in the Ac samples, this supports that it was likely not being present versus a failure to
162 detect it. Together, these results supported that the ELISA could be used to directly compare
163 changes in most of the cytokines between species.

164

165 **Fibrotic repair is associated with elevated amounts of circulating IL-5, IL-6 and CCL3.**

166 Using our cytokine assay, we first compared circulating serum cytokine concentrations
167 from uninjured animals among groups (species and source population) to establish a systemic
168 baseline for each group (Figure 1A). A total of 13 cytokines were compared as CSF2 was not
169 present in the serum of any species. While many baseline concentrations were similar between
170 groups, immune-challenged animals (i.e., wild) exhibited higher IL-4, IL-6, CCL2, and TNF α
171 compared to laboratory-reared animals (Figure 1A). Interestingly, the Mm-Kenya animals were
172 a transitional group between Mm-UKY and Mm-Wild for TNF α and IL-4 (Figure 1A).
173 Heightened concentrations of IL-6, TNF α and IL-4 support previous pathogen exposure and a
174 possibility of current infection [43, 44]. Thus, Mm-Kenya, Mm-Wild and Ap had a relatively
175 activated immune system, while Mm-UKY and Ac possessed a more naïve immune system [45].
176 There were no consistent differences between regenerators and non-regenerators (Figure 1A).

177 Next, we quantified the systemic injury response for each cytokine compared to its
178 baseline, beginning 24 hr (D1) after injury and over the next twenty days (Figure 1B). In most
179 cases (except IL-2, IL-6, IL-17 and CXCL1), there was no effect of day (Supplemental Table 2),
180 indicating that the immediate systemic response persisted for 20 days. Animals with a more
181 naïve immune system showed increased IL-2 and TNF α , and decreased IL-1 α compared to a
182 relatively activated immune system (Figure 1B: solid lines compared to intermittent lines and
183 Supplemental Data File). Regeneration showed decreased IL-5, IL-6, IL-17, CCL3 and CXCL1
184 compared to fibrotic repair (Figure 1B: red lines compared to black lines and Supplemental Data
185 File). This latter result supported that animals healing by fibrotic repair and regeneration could
186 be separated by their systemic response to injury.

187

188 **A regenerative microenvironment is marked by induction of T-cell-associated cytokines**
189 **and a dampened pro-inflammatory cytokine response.**

190 Resident cells and infiltrating immune cells secrete cytokines that likely polarize the
191 injury microenvironment to support regeneration or fibrotic repair [12, 13, 15, 16, 34, 46, 47].
192 Thus, to quantify local cytokine concentrations we assayed tissue lysate collected throughout the
193 healing response. IL-1 α could not be compared because baseline concentrations were above the
194 upper limit of quantification in more than 80% of samples, indicating that IL-1 α in the ear pinna
195 was at least two orders of magnitude greater than the other cytokines measured. Although ear
196 pinna tissue is structurally similar across species [40], local cytokines in *Acomys* were
197 consistently detected at lower concentrations compared to *M. musculus*. Moreover, because the
198 concentration of cytokine may not be as important as the dynamics of the cytokine, we compared
199 the change in cytokine compared to baseline over 20 days (Figure 2). Injury elicited significant

200 changes over time compared to baseline for all cytokines measured in tissue lysate supporting a
201 dynamic response (Supplemental Table 3). Furthermore, while most cytokines shared similar
202 trajectories over time, there was an effect of Group and the Group*Day interaction for all
203 cytokines supporting significant differences in the magnitude of change among the groups
204 (Figure 2 and Supplemental Table 3). Supporting an inflammatory response in all groups,
205 several pro-inflammatory cytokines (IL-6, TNF α) and myeloid chemotactic factors (CCL3, CSF2
206 and CXCL1) showed an increase compared to baseline between D1 and D3 that then decreased
207 to baseline or below between D5 and D20 (Figure 2). There was also an overall decrease
208 compared to baseline for IL-5 and a small but significant change from baseline for IL-2 and IL-4
209 across all groups (Figure 2). Animals with naïve immune responses had a stronger increase in
210 CCL3 and a smaller increase for CCL2 and CXCL1 compared to activated immune responses
211 (Figure 2: solid compared to intermittent lines). We also identified several cytokines that
212 showed differential changes between regeneration and fibrotic repair that we describe below
213 (Figure 2: red compared to black lines).

214 During the acute inflammatory phase (D1 and D2), CCL2 and CXCL1 were increased 9
215 and 12-fold during fibrotic repair compared to regeneration, respectively (Figure 3). IL-6
216 showed a similar result at D2 where Mm-UKY, Mm-Kenya and Mm-Wild were increased 10-
217 fold compared to Ac and Ap (Figure 3). Additionally, IL-17 was increased in Ap, but decreased
218 in Mm-UKY and Mm-Kenya and IL-12 was increased in Ap compared to all *Mus* (Figure 3).
219 Interestingly, the TNF α response—a biomarker of inflammation—could not reliably separate
220 fibrotic repair and regeneration (Figure 3).

221 Regardless of healing outcome, re-epithelialization occurs by D10 [40, 42] coincident
222 with resolution of many pro-inflammatory cytokine responses (Figure 1B and 2: yellow bars).

223 While there were some differences among groups for the timing of resolution, IL-1 β , TNF α , and
224 CCL2 were similar to or below baseline at D10 for each species (Figure 3). IL-6 also followed
225 this pattern; however, there was a differential response where Ac remained elevated through D20
226 while all other species decreased below baseline (Figure 3).

227 At D20, during tissue morphogenesis, the only cytokines that showed a differential
228 response were IL-12 and IL-17 that were increased during regeneration compared to fibrotic
229 repair (Figure 3). The anti-inflammatory cytokine IL-4 did not differ over time with respect to
230 regenerative ability, suggesting that the differences in pro-inflammatory cytokine release is likely
231 not an IL-4 mediated response. Our results suggest that subtle differences in how cytokines are
232 deployed in the injury microenvironment can distinguish regeneration or fibrotic repair. These
233 data suggest that strong, acute increases in the pro-inflammatory cytokines IL-6, CCL2 and
234 CXCL1 are associated with fibrosis, while the release of IL-12 and IL-17 during tissue
235 morphogenesis is associated with regeneration.

236

237 **Regeneration is associated with an early burst of T cell influx to the injury site.**

238 The release of IL-12 and IL-17 into the regenerative microenvironment suggested
239 enhanced T cell activation during regeneration [48, 49]. Therefore, we quantified T cell influx
240 into uninjured and healing tissue from our laboratory populations of *Mus* (Mm-UKY) and
241 *Acomys* (Ac) using flow cytometry with an antibody to the extracellular portion of the T cell
242 marker CD3. We observed significant differences in CD3⁺ cells in injured tissue between
243 species over time (two-way ANOVA, n=57; species: Df=1, F=49.49 $P < 0.001$; day: Df=6,
244 F=89.07, $P < 0.001$; species*day: Df=6, F=21.49 $P < 0.001$) (Figure 4A). In uninjured tissue,
245 Mm-UKY had 10-times more CD3⁺ cells compared to Ac (Tukey-Kramer HSD post-hoc test,

246 Df=6, $t=6.21$, $P<0.001$) (Figure 4A). While the total number of CD3⁺ cells that infiltrated the
247 wound was higher in Mm-UKY compared to Ac, there was a greater fold change relative to D0
248 for CD3⁺ cells during regeneration compared to fibrotic repair (Figure 4B). Ac exhibited a
249 monophasic response to injury starting on D1 with a 78-fold influx of T cells that peaked on D3
250 and remained above baseline at D15. Mm-UKY showed a biphasic response with peak influx of
251 10-fold at D7 that returned to baseline at D15 (Figure 4B). Importantly, at D15, when IL-12 was
252 increased (Figure 2), the influx of CD3⁺ cells remained high in Ac compared to Mm-UKY
253 (Figure 4B).

254 We next used immunohistochemistry with an antibody specific to the intracellular portion
255 of the CD3 receptor to assess the spatial distribution of T cells during acute inflammation and
256 morphogenesis (Figure 4C-E). First, these data confirm the greater influx of CD3⁺ cells at D5
257 and D15 in Ac compared to Mm-UKY (Figure 4C-E). Second, in Mm-UKY most CD3⁺ cells
258 were associated with the epidermis and were rarely observed distal to the amputation plane
259 (Figure 4C). On the other hand, CD3⁺ cells in Ac were present in the epidermis and dermis, and
260 regularly observed in healing tissue distal to the amputation plane (Figure 4E). At D15, CD3⁺
261 cells were found in the epidermis and dermis of both species (Figure 4D, F). Interestingly,
262 CD3⁺ cells associated with the epidermis in Mm-UKY (Figure 4G) exhibited a spindle-shape
263 morphology compared to a rounded shape in Ac (Figure 4H). There also appeared to be more
264 CD3⁺ cells in the dermis of Ac compared to Mm-UKY (Figure 4D, F), and the CD3⁺ cells
265 tended to localize near regenerating hair follicles in Ac (Figure 4I). Attempts to characterize
266 individual T cell phenotypes during regeneration using flow cytometry and IHC using 19
267 commercially available antibodies, supported significant differences in antibody-epitope binding
268 between species that prevented further T cell phenotyping by receptor subtype in *Acomys*

269 (Supplemental Table 5). Therefore, we interrogated a comparative injury RNAseq dataset for
270 differential expression of T cell associated transcripts between *Mus* and *Acomys* [40]. While
271 expression for genes associated with non-lymphocyte immune cell populations were generally
272 similar between species, several transcripts associated with T cells and natural killer cells were
273 increased in *Acomys* and decreased in *Mus* in response to injury (Figure 4J). Increased
274 expression of *Cd8*, *Ctla4*, *Il2ra*, *Foxp3*, and *Tnfrsf4* specifically suggested an activated cytotoxic
275 and regulatory T cell response during regeneration but not fibrotic repair (Figure 4J). During
276 fibrotic repair, *Cd4* was differentially increased at D5 and D10 suggesting the presence of CD4
277 helper T cells not present during regeneration (Figure 4J). Together, these data demonstrate that
278 regeneration was associated with a proportionally greater influx of CD3+ cells that accumulate
279 quickly at the injury site and that specific subtypes of activated T cells were preferentially
280 associated with regeneration.

281

282 **STAT3 is activated independently from IL-6 during blastema formation**

283 We also sought to test our observation that strong induction of the pro-inflammatory
284 cytokine IL-6 was associated with the acute inflammatory phase of fibrotic repair. To do this,
285 we assayed for IL-6 signaling using STAT3 phosphorylation (Figure 5A-F). STAT3 is
286 phosphorylated in response to the ligand IL-6 binding its membrane receptor, which activates
287 signal transduction in target cells [50]. Corroborating our ELISA quantification for IL-6 in the
288 tissue microenvironment, we found that pSTAT3 increased 8-fold in response to injury in Mm-
289 UKY during the acute inflammatory phase (Figure 5A, B). Similarly, during fibrosis when IL-6
290 concentrations resolved in Mm-UKY, pSTAT3 began to decline toward baseline (Figure 5A, B).
291 In *Acomys*, pSTAT3 was significantly elevated at D1, although to a lesser extent than compared

292 to Mm-UKY (Figure 5A, B). Moreover, during blastema formation (D10-15) when our ELISA
293 data showed increased IL-6 compared to baseline in Ac (Figure 3), analysis of pSTAT3 showed
294 further induction of pSTAT3 in Ac (Figure 5A, B).

295 To determine the cellular localization of STAT3 phosphorylation, we assayed for
296 pSTAT3 using immunohistochemistry during the acute inflammatory phase (D2) and new tissue
297 formation (D15) (Figure 5C-F). Supporting the immunoblot data, both species showed extensive
298 nuclear staining for pSTAT3 at D2 in the epidermis and mesenchymal compartments (Figure
299 5C', D'). Positive staining in the epidermis > 200 μ M proximal to the amputation plane
300 suggested STAT3 activation was a pervasive response to injury within the ear pinna in both
301 species (Figure 5C, D). Supporting the 2-fold difference in pSTAT3 we observed between Mm-
302 UKY and Ac (Figure 5A, B), we found that nearly every epidermal cell in Mm-UKY appeared
303 positive for pSTAT3 whereas less than half of the epidermal cells were positive in Ac (Figure
304 5C', D'). The internal tissue compartments (e.g., dermis, cartilage, muscle and adipose) at D2
305 were similar between species with approximately half of the total cells positive for pSTAT3. At
306 D15, only a few pSTAT3 positive cells were present in Mm-UKY and they were isolated to the
307 epidermis distal to the amputation plane (Figure 5E, E'). In contrast, pSTAT3 positive cells
308 were widespread throughout the blastema in Ac (Figure 5F, F'). Together, these data support
309 stronger IL-6 mediated STAT3 activation in Mm-UKY compared to Ac during the acute
310 inflammatory phase and increased STAT3 activation during blastema formation.

311 Greater increases in IL-6 and CXCL1 during the acute inflammatory phase of fibrotic
312 repair in *M. musculus* suggested that these molecules might antagonize a potential regenerative
313 response. Previous studies have shown that a balance in these molecules regulate wound healing
314 as IL-6 and CXCL1 are potent pro-inflammatory molecules and hyper-elevated concentrations

315 after injury are attributed to aberrant healing and chronic inflammation [51-53]. Additionally,
316 genetic ablation of *IL-6*, the *IL-6 receptor*, or the *CXCL1 receptor (CXCR2)*, causes severely
317 delayed re-epithelialization, scab formation and abhorrent wound healing in cutaneous and
318 incisional wounds [54-57]. IL-6 signaling activates several downstream mediators of
319 inflammation including cyclooxygenase-2 (COX-2), and its enzymatic products can amplify the
320 inflammatory response [58]. To test if COX-2 activity promotes fibrosis in the ear pinna, we
321 used our ear punch assay in Mm-UKY treated healing tissue with Celecoxib, a specific and
322 potent COX-2 inhibitor [59] (Figure 6A). Comparing ear-hole closure between celecoxib- and
323 vehicle-treated animals there was no support for a difference in the rate of closure (D5 through
324 D30) (repeated measures two-way ANOVA, $n=31$; treatment: $Df=1$, $F=2.42$, $P=0.137$; day:
325 $Df=5$, $F=179.62$, $P<0.001$; treatment*day: $Df=5$, $F=0.36$, $P=0.875$) (Figure 6B). Similarly,
326 comparison of ear-hole area at D64 showed no support for a difference between treatment and
327 control ears (unpaired t-test; $t=0.671$, $P=0.512$) (Figure 6C). One out of five celecoxib-treated
328 animals had not completed re-epithelialization by D10 (Figure 6D-F). Lastly, while the intensity
329 of Picrosirius stain appeared to be lower in celecoxib treated animals compared to controls, there
330 was no difference in the area of collagen deposition at D64 (unpaired t-test, $t=0.104$, $P=0.918$)
331 (Figure 6G-I). Thus, these data support that systemic inhibition of COX-2 activity is not
332 sufficient to reduce fibrosis or induce a regenerative response after ear pinna injury in *M.*
333 *musculus*.

334 DISCUSSION

335 In this study, we performed a comprehensive cytokine characterization of the immune
336 response to injury where identical injuries in closely-related species undergo two different
337 healing responses: regeneration or fibrotic repair. Importantly, our experimental design
338 leveraged a comparison of animals with an activated and naïve immune system in order to
339 identify species-specific cytokine changes that were associated with regeneration and not due to
340 an environment-immunity interaction. Our analyses showed that regardless of healing outcome,
341 injury induced a common set of pro-inflammatory factors (IL-6, and TNF α) and chemokines
342 (CCL3, CSF2 and CXCL1) during the acute inflammatory phase of fibrosis and regeneration.
343 Additionally, we observed similar responses between healing outcomes for IL-2, IL-4 and IL-5
344 in the tissue microenvironment. While this supports that fibrotic repair and regeneration share
345 inflammation during the healing process, we also found significantly greater responses for IL-6,
346 CCL2 and CXCL1 during fibrotic repair compared to regeneration. In contrast, regeneration was
347 uniquely associated with local increases in IL-12 and IL-17. Supporting our cytokine analysis,
348 we found that regeneration was associated with a strong influx of T cells during acute
349 inflammation compared to fibrotic repair and that regeneration-competent T cells were closely
350 associated with the dermis during blastema formation. This latter point suggests that T cells may
351 influence local inflammation and contribute to the local regulation of tissue morphogenesis in
352 spiny mice.

353 Recent studies comparing immune profiles between laboratory-reared and pet-store or
354 wild-caught *M. musculus* demonstrate that non-laboratory strains have more CD44⁺ effector T
355 cells, memory T cells and circulating neutrophils [60, 61]. Although neither group directly
356 measured serum cytokines from the different populations, the elevated baseline concentrations of

357 IL-4, IL-6, CCL2 and TNF α that we measured in circulation from immune-challenged animals
358 support larger active populations of effector and memory T cells. These data support that our
359 immune-challenged group have been exposed to more pathogens than the laboratory-reared mice
360 which is undoubtedly the case. In addition to the increased baseline concentrations of these
361 cytokines, we also found significant differences in the response to injury for IL-1 α , IL-2 and
362 TNF α between animals with an activated or naïve immune system. Studying wild-caught
363 populations enabled us to identify responses that accurately reflected phenotypic differences
364 between species, rather than differences that could be explained by immune status. Of particular
365 importance was our inclusion of wild-caught *A. percivali* that indicate increases in TNF α , CCL2
366 and CXCL1 are not inhibitory to regeneration. Additionally, we observed high variation in
367 cytokine concentrations across our dataset, indicating that the immune response to injury could
368 be confounded by individual variation. In other words, researchers should not expect to identify
369 clear transition phases based on time after injury with small sample sizes. Ultimately these data
370 support that injury elicits a local cytokine response that is dependent of baseline immune status
371 with respect to release of cytokines that in turn effects the timing of events but does not change
372 healing outcome.

373 Acute inflammation is a necessary component of the innate immune response designed to
374 fight invading microbes by recruiting leukocytes from circulation and activating local myeloid
375 and lymphoid cells. Our analyses demonstrate that injury induces an acute inflammatory
376 response regardless of healing outcome that resolves within ~10 days; a timeframe in line with
377 human and rodent wound healing studies [7, 62]. In particular, we found the local release of
378 CCL3, CSF2 and CXCL1 in all groups, which are known to be potent chemokines for
379 monocytes, macrophages and neutrophils. Moreover, the local release of IL-6 and TNF α

380 supports the presence of activated macrophages and neutrophils as a common injury response.
381 Supporting our previous work that neutrophils infiltrate injured spiny mouse tissue slower
382 compared to laboratory mice [15], regeneration was associated with delayed release and a
383 reduced maximal fold change in IL-6 and CXCL1 compared to fibrotic repair. Additionally, we
384 did not detect a CCL2 response during regeneration, and IL-6, CXCL1 and CCL2 are known to
385 positively regulate the speed of re-epithelialization [54-56], which we find to be delayed at most
386 five days in *A. cahirinus* compared to *M. musculus* [40]. Thus, while acute inflammation is a
387 component of regeneration and fibrotic repair, the cellular differences are likely attributed to
388 reduced pro-inflammatory cytokines released into the microenvironment.

389 Corroborating our observation that the IL-6 response was weaker during regeneration
390 compared to fibrotic repair, we found diminished activation of STAT3 during acute
391 inflammation (D1-10) in spiny mouse epidermis compared to mouse. Interestingly, we observed
392 an increase in pSTAT3 during blastema formation, whereas pSTAT3 levels declined during
393 fibrotic repair. Furthermore, during tissue morphogenesis at D15 many blastemal cells were
394 STAT3 positive. Given that IL-6 concentrations did not appreciably increase during blastema
395 formation or tissue morphogenesis the increase in STAT3 activity is likely independent of IL-6.
396 STAT3 is activated through multiple pathways (e.g. leukemia inhibitory factor, epidermal
397 growth factor, palette derived growth factor, IL-10, IL-17, etc.). Although IL-17 increased in *A.*
398 *percalli* after D10, it did not increase in *A. cahirinus* suggesting it is not responsible for the late
399 phase of STAT3 phosphorylation. Given that STAT3 signaling is multifaceted, one potential
400 biological link is that STAT3 activity is necessary for satellite-cell activation and axon
401 regeneration in mammals [63-65]. Interestingly, the expression of *Sal4*—a factor necessary for
402 blastema maintenance in *Xenopus* and *Ambystoma*—is regulated by pSTAT3 [66-68]. While

403 *Sal4* does not have a mammalian homolog, this data supports that activation of STAT3 in
404 regenerating tissue is an evolutionary conserved mechanism and interrogating unique STAT3
405 targets in spiny mice may uncover mechanisms that regulate blastema formation in mammals.

406 Inhibition of downstream signaling induced by IL-6 / CXCL1, such as arachidonic acid
407 metabolism by COX-2, has been shown to reduce fibrosis post epidermal injury (e.g. incisional,
408 cutaneous and chronic pressure wounds) [69-71]. Celecoxib treatment to inhibit COX-2 in the
409 present study may have slowed re-epithelialization. Additionally, while the total area of fibrosis
410 was not different between celecoxib- and vehicle-treated animals there appeared to be a small
411 reduction in the total amount of collagen produced in celecoxib-treated animals from reduced
412 intensity of picrosirius staining. However, similar to previous reports, reduction in COX-2
413 activity did not induce regeneration, supporting that inflammation is not the ultimate inhibitory
414 barrier.

415 In addition to the magnitude increase in IL-6 and CXCL1, our analyses found that
416 increased local CCL2 was specific to fibrotic repair. CCL2 was first identified as a monocyte-
417 specific chemoattractant to sites of injury and infection, and activates macrophages [72, 73].
418 CCL2 also attracts neutrophils and supports neutrophil-dependent tissue damage [72]. As such,
419 the amount of CCL2 that is released into an injury microenvironment regulates the healing
420 response and studies support there is a positive relationship between CCL2 and the amount of
421 fibrosis during fibrotic repair [74-76]. However, a careful balance must be maintained as CCL2
422 knockout mice do not heal wounds [77]. Thus, it is possible that the reduced IL-6, CCL2 and
423 CXCL1 responses are responsible for reduced fibrosis in spiny mice. Although these key factors
424 appear to interact in the hierarchy of the progression of fibrotic repair, the paracrine mechanism

425 of how they would activate dermal fibroblasts remains unknown. It is likely another cell-type,
426 such as a macrophage or T cell, is mediating the signal.

427 In addition to this study, two studies have quantified cytokines during regeneration—one
428 in axolotl limbs [12] and the other in spiny mouse dorsal skin wounds [34]. Godwin et al. (2013)
429 used a mouse cytokine array to analyze regenerating salamander limbs and found that all but two
430 cytokines detected reached peak amounts within 48hrs of injury and that every cytokine returned
431 to baseline by D15 after a blastema had formed. Brant et al. (2016) used the same cytokine array
432 to assess cytokines during the first 14 days of spiny mouse dorsal skin regeneration and observed
433 a similar phenomenon and all detected cytokines resolve to baseline by D14. Despite study-
434 specific differences in the ability to detect antigens and a lack of parallelism validation, these
435 studies support that release of CCL3 and TNF α in tandem with a differential inflammatory
436 response occurs prior to tissue regeneration. However, our comparative analyses also suggested
437 that the magnitude of the increase in IL-6 and CXCL1 might serve as early indicators of a
438 fibrotic repair trajectory. For example, the IL-6 response to injury, although present, was small
439 and CXCL1 did not respond during both axolotl limb and spiny mouse skin regeneration.

440 Finally, our cellular analysis uncovered a surprisingly rapid adaptive immune response
441 measured as an early influx of T cells in regenerating compared to non-regenerating species.
442 Importantly, our findings support that the arrival of T cells in spiny mice is concurrent with the
443 arrival and proliferation of monocytes [15], which suggests there is a regenerative-competent T
444 cell response that is different from a fibrotic T cell response. Contrary to hypotheses suggesting
445 that a strong adaptive immune response reduces regenerative ability [78, 79], our findings
446 suggest T cells may positively regulate regeneration in spiny mice. Similar to macrophages, T
447 cells can differentiate into a number of functional subpopulations which differentially affect cells

448 in the inflammatory microenvironment [80]. Our analysis of the transcriptional response to
449 injury between *M. musculus* and *A. cahirinus* suggests that fibrotic repair is associated with an
450 accumulation of inactivated T_H cells, while during regeneration there is an accumulation of
451 activated cytotoxic T and regulatory T (T_{REG}) cells. Studies have shown that loss of cytotoxic
452 CD8⁺ T cells inhibits skeletal muscle regeneration, accelerates bone fracture healing, and
453 increases fibrosis in incisional wounds [81-87]. Additionally, recent work showed that T_{REG}
454 populations infiltrate injured muscle quickly after injury and are necessary to regulate the ratio of
455 MHC-class II positive and negative macrophages present in the injured tissue. When the T_{REG}
456 population is ablated subsequent regeneration is impaired [17]. Moreover, spiny mice have a
457 greater NADPH oxidase induced ROS response [15], which can be partially controlled by T_{REG}
458 cells [88-90]. Thus, these studies support an anti-fibrotic role for T cells and suggest the action
459 of cytotoxic T and T_{REG} cells may have a positive role during spiny mouse epimorphic
460 regeneration.

461 Together, the data presented here support that tissue regeneration in *Acomys* occurs in
462 cooperation with an adaptive immune response and that lymphocyte phenotype might play a key
463 role in facilitating a regenerative or fibrotic response. Ongoing studies in our laboratory are
464 aimed at characterizing the macrophage and T cell populations that are associated with the
465 injured tissue during regeneration and fibrotic repair. These future datasets (and the present one)
466 will create a framework to begin testing how the immune response functions during complex
467 tissue regeneration in a mammalian model. We believe that modulating the immune response at
468 the injury microenvironment will be an essential piece to inducing epimorphic regeneration in
469 tissues that naturally heal by fibrotic repair.

479 **ACKNOWLEDGEMENTS**

480 We thank Adam Cook, Chanung Wang, Bailey Gensheimer, Malik Guidry, John Ewoi and
481 Stanley Marete for help with live-trapping, animal care and data collection. We also thank Peter
482 Jessel and the Tomlinson family for kindly allowing us continued access to their property in
483 Kenya. We acknowledge David Higginbotham, Jim Monegue and rest of the swine unit for their
484 help and enthusiasm with trapping the wild *Mus musculus*. Funding for this work was provided
485 by the National Science Foundation (NSF) and the Office for International Science and
486 Engineering (OISE) to A.W.S. (IOS-1353713) and V.O.E (IOS-1353857). The University of
487 Kentucky provided additional funding to A.W.S.

489 **DECLARATION OF INTERESTS**

490 The authors declare no competing interests.

491

492 **FIGURE LEGENDS**

493 **Figure 1 Ability to regenerate and immunity-status are associated with specific systemic**
494 **immune profiles and immune responses to injury. (A)** Comparison of cytokine
495 concentrations in serum from uninjured animals showed higher concentrations of IL-4, IL-6,
496 CCL2 and TNF α in wild-caught animals compared to laboratory-reared animals indicated that
497 wild animals have a “primed” immune system. No difference was found between non-
498 regenerators (Mm-UKY, Mm-Kenya and Mm-Wild) and regenerators (Ac and Ap). Data
499 represent box and whiskers with median, interquartile range and individual data points. N/A
500 denotes concentrations could not be quantified in any animal of the group. The dashed line in
501 each graph represents the lower limit of detection for the specific cytokine. N/S denotes $P>0.05$
502 for One-way ANOVA (See Supplemental Table 1) and different letters above the data denotes
503 $P\leq 0.05$ for Tukey-Kramer pairwise comparisons (See Supplemental File). **(B)** The change in
504 systemic cytokines compared to D0 over 20 days after ear hole punch. A naïve immune system
505 response (solid lines) was consistent with increased IL-2 and TNF α , and decreased IL-1 α
506 compared to a primed response (intermittent lines) (See Supplemental Table 2). Fibrotic repair
507 (black) was associated with increases in IL-5, IL-6, IL-17, CCL3 and CXCL1 compared to
508 regeneration (red). Data represent mean and S.E.M. for at least n=5 animals per species per
509 timepoint. The dashed line at Y=1 represents no change compared to D0 and the yellow boxes
510 represent the inflammation resolution window.

511 **Figure 2 The tissue microenvironment is dynamic, and the ability to regenerate is**
512 **associated with a specific immune response to injury.** The comparison of the change in
513 cytokines from tissue lysate compared to D0 over 20 days after ear hole punch. All cytokines
514 varied over time and between groups (See Supplemental Table 3). There was a stronger increase
515 in CCL3 a muted increase for IL-12 and CXCL1 in immune-naïve (solid lines) compared to
516 immune-primed animals (intermittent lines). Non-regenerators (black) had stronger increases for
517 IL-6, CCL2 and CXCL1 compared to regenerators (red). Additionally, IL-17 decreased in non-
518 regenerators and increased in regenerators. Data represent mean and S.E.M. for at least n=5
519 animals per species per timepoint. The dashed line at Y=1 represents no change compared to D0
520 and the yellow boxes represent the inflammation resolution window.

521 **Figure 3 Regeneration is associated with specific temporal cytokine responses in the tissue**
522 **microenvironment.** The comparison of the change in cytokines from tissue lysate compared to
523 baseline. Non-regenerators (Mm-UKY, Mm-Kenya, and Mm-Wild: Black) show a stronger
524 response compared to regenerators (Ac and Ap: Red) for several inflammatory cytokines during
525 the immediate response, acute inflammatory phase. These differences mostly resolved at day 10
526 and 20. In contrast, regenerators showed a stronger IL-12 and IL-17 response during tissue
527 morphogenesis. Data represent box and whiskers with median, interquartile range and individual
528 data points. N/A denotes concentrations could not be quantified. The dashed line at Y=1
529 represents no change compared to D0. Each graph showed $P<0.05$ for effect of group using a
530 One-way ANOVA on log-transformed data (See Supplemental Table 4) and different letters
531 above each group denotes $P<0.05$ for Tukey-Kramer pairwise comparisons (See Supplemental
532 File).

533

534 **Figure 4 The regeneration microenvironment is primed by greater T cell influx and**
535 **activated T_{REG} signature. (A)** Comparison of total CD3⁺ cells quantified by flow cytometry
536 from disassociated ear pinna and **(B)** the ratio relative to uninjured tissue for *M. musculus* (black)
537 and *A. cahirinus* (red). Data represent mean and S.E.M. and n=4 or 5. An * denotes $P < 0.05$ for
538 pairwise comparison within the day between species for Tukey-Kramer HSD posthoc test. **(C-I)**
539 Representative immunohistochemistry for CD3 (red) counterstained with DAPI (gray) at the
540 proximal wound margin (amputation plane can be determined from the end of the cartilage—
541 indicated by the dotted line) from D5 and D15 after injury of *M. musculus* (C, D) and *A.*
542 *cahirinus* (E, F). More T cells (yellow arrowhead) were present throughout the wound bed and
543 were mainly found in the dermis of *A. cahirinus* compared to *M. musculus*. The T cells
544 associated with epidermis (boundaries indicated by the dotted line) tended to be spindle-like in
545 *M. musculus* (G), while rounded in *A. cahirinus* (H). The dermal T cells in *A. cahirinus* also
546 tended to be in close proximity to regenerating epidermal appendages (I). N=4 and bar equals
547 200 μm (C-F) or 20 μm (G-I). **(J)** Heatmap of differential gene expression compared to
548 uninjured tissue suggests that the regeneration microenvironment contains a substantial NK,
549 CD8⁺ and T_{REG} cell response while fibrotic repair has a CD4⁺ cell response. Data comes from a
550 previously published analysis [40].

551

552 **Figure 5 Time-dependent STAT3 activation in the blastema is associated with regeneration.**
553 **(A-B)** Comparison of representative immunoblots for pSTAT3 and ACTB for indicated time and
554 species from injured tissue homogenate from ear-hole punch assay (A). Fibrotic repair is
555 associated with strong early STAT3 activation while regeneration is associated with a weak early
556 and strong postponed activation (B). Data represent mean fold change of pSTAT3 intensity
557 normalized to ACTB intensity and relative to D0 and S.E.M. n=4 individuals per time point and
558 species (B). **(C-F)** Representative images for immunohistochemistry for pSTAT3 (Brown)
559 counterstained with hematoxylin (Blue) for *M. musculus* (C, C', E and E') and *A. cahirinus* (D,
560 D', F and F') at the indicated time points. On D2 after injury, nearly every epidermal cell in *M.*
561 *musculus* was positive compared to about half in *A. cahirinus* (C, D). On D15 after injury, only
562 a small population of epidermal cells in *M. musculus* were positive compared to about half in *A.*
563 *cahirinus* (E, F). Additionally, about half of the cells in the forming blastema remain positive at
564 D15. Data represent n=3, and bar equals 200 μm .

565

566 **Figure 6 COX-2 inhibition does not liberate regeneration in *M. musculus*.** **(A)** Celecoxib
567 treatment during the first 10 days of injury reduces secondary inflammation caused by IL-6 and
568 CXCL1. **(B-C)** Celecoxib treatment did not affect the rate of ear-hole closure from D5 to D30
569 (B), or ear-hole area at D64 (C). **(D-F)** Mason's trichrome stain on D10 ear tissue from control
570 (D) and treatment (E) showed 20% of the distal injury plane from treated ears were not re-
571 epithelialized, while 100% of control treated ears and the proximal injury plane were re-
572 epithelialized (F). **(G-I)** Picosirius stain on D64 ear tissue from control (G) and treatment (H)
573 showed no difference in the total collagen fibrotic area distal to the amputation plane (I). Data
574 represent mean \pm S.E.M. and the lines represent cubic regression for n=10 per treatment (B),
575 OR individual data (red dots) and median and interquartile range for n=10 per treatment (C, I).
576

577 TABLES

578 **Table 1:** Comparison of cytokine slopes from parallelism test of cytokine assay. This was used
 579 to determine which species and source comparisons could be made for each cytokine in the
 580 Comparison column.

Antigen	Standard	Sample	<i>Mus musculus (Mm)</i>	<i>Acomys cahirinus (Ac)</i>	<i>Acomys percivali (Ap)</i>	Comparison

587

588 MATERIALS AND METHODS

589 *Animals*

590 *Mus musculus* (Mm-UKY) and *Acomys cahirinus* (Ac) were maintained at our animal
591 facility at the University of Kentucky, Lexington, KY, USA. Mm-UKY were sexually mature
592 (10- to 12-week old), female, outbred Swiss Webster (ND4, Envigo, Indianapolis, IN). They
593 were housed at a density of 2-4 individuals in static IVC cages with pine shavings and given
594 autoclaved water and 18% protein mouse chow (Tekland Global 2918, Envigo). Ac were
595 sexually mature (12- to 28-weeks old), males and females and were housed at a density of 10-15
596 individuals in large metal wire cages (24 inch x 12 inch x 14 inch, height x width x depth,
597 Quality Cage Company, Portland, OR) with pelleted pine bedding (Southern States Cooperative,
598 Inc., Richmond, VA) and given autoclaved water and a 3:1 mixture by volume of 14% protein
599 mouse chow (Teklad Global 2014, Envigo) and black-oil sunflower seeds (Pennington Seed Inc.,
600 Madison, GA) [91]. Additionally, the air within facility was filtered, and the animals were
601 exposed to natural light through large windows (approximately 12h:12h L:D light cycle during
602 the experiment). All Mm-UKY and Ac samples were collected between 9/20/2015 and
603 10/28/2015.

604 Wild *M. musculus* (Mm-Wild) were live trapped at the C. Oran Little Research Center in
605 Versailles, KY (38°4'N, 84°44'W) and maintained in an alternate animal facility at the
606 University of Kentucky. Mm-Wild were housed at a density of 10-12 individuals in large metal
607 wire cages with pelleted pine bedding and given autoclaved water and 18% protein mouse chow.
608 The animals acclimated to captivity for at least twenty-one days before any experiments were
609 started. The air within the facility was filtered and the animals were exposed to a 12:12h L:D

610 cycle by fluorescent lights. All Mm-Wild samples were collected between 4/1/2017 and
611 6/21/2017 and 12/12/2017 and 3/6/2018.

612 The Kenyan *M. musculus* (Mm-Kenya) were sexually mature (10- to 12-week old),
613 female, outbred Swiss Webster mice obtained from a local breeder in Nairobi, Kenya and
614 maintained in an animal facility at the University of Nairobi, Kenya. Sexually mature *Acomys*
615 *percivali* (Ap) were live-captured at Mpala Research Centre in Laikipia, Kenya (0°17'N,
616 37°52'E), and transported to the University of Nairobi for study. Each species was separated by
617 sex and housed at a density of 10-15 animals in large metal wire cages, given tap water, fed
618 mouse pencils (Argroside Inc., Nairobi, Kenya) 1x per day and exposed to natural light through
619 windows (equivalent 12h:12h L:D cycle). The animals acclimated to captivity for at least
620 twenty-one days before any experiments were started. Additionally, the facility was open to the
621 natural environment (i.e., the mice were exposed to Nairobi air) and cool nighttime temperatures
622 were supplemented with ceramic heaters. Mm-Kenya samples were collected between
623 6/04/2015 and 7/04/2015 and Ap samples were collected between 5/04/2015 and 7/04/2015, and
624 between 5/02/2016 and 6/04/2016.

625 All animal trapping and procedures were approved by the University of Kentucky
626 Institutional Animal Care and Use Committee (IACUC) under protocol 2013-1119, Kenyan
627 Wildlife Service (KWS), and the University of Nairobi Faculty of Veterinary Medicine Animal
628 Care and Use Committee (FVM ACUC). Research in Kenya was approved by the Kenyan
629 National Council for Science and Technology (NACOSTI). All wild species trapped were
630 species of least concern.

631

632 ***Sample collection and preparation***

633 We used a 4 mm biopsy punch to create a hole through the ear pinna, as previously
634 described [40]. Healing ear tissue was collected on D0, 1, 2, 3, 5, 10, 15 and 20. To minimize
635 circadian effects, animals were injured between 10:00 and 12:00, and samples were collected
636 between 11:00 and 15:00. Animals were deeply anesthetized with 5% (v/v) isoflurane and a
637 maximal amount of blood was collected by cardiac puncture using a 25-gauge needle. An 8 mm
638 biopsy punch was used to harvest healing ear tissue.

639 To isolate serum, blood was collected into a serum separator tube (#454243, Greiner bio-
640 one, Kremsmünster, Austria) and allowed to clot for at least 45 minutes, followed by
641 centrifuging at 3,000 x g for 10 minutes. Serum was aliquoted and stored at -80°C or on dry ice
642 until analysis. The tissue was used for two downstream assays, histology and cytokine
643 quantification. For histology, one of the 8 mm biopsies was placed into 10% (v/v) neutral
644 buffered formalin (American MasterTech, McKinney, TX) overnight, dehydrated, embedded in
645 paraffin and cut to 5 µM thickness on a rotary microtome. For cytokine quantification, a ring of
646 tissue closest to the injury approximately 1 mm wide was snap frozen in liquid nitrogen or a
647 slurry of dry ice and ethanol, and then stored at -80°C or on dry ice. Next, the tissue was
648 homogenized in RIPA buffer supplemented with protease and phosphatase inhibitors (#24948,
649 Santa Cruz Biotechnology, Inc. Dallas, TX; #78427, Thermo Scientific) using ceramic beads
650 (Matrix D, MP Biomedicals, LLC, Solon, OH) and a bead mill for 5 minutes (Next Advance,
651 Inc., Troy, NY), centrifuged at 10,000 x g for 15 minutes to pellet insoluble protein, and the
652 soluble protein was separated into a new tube. The total protein was quantified by bicinchoninic
653 acid assay (#23225, Thermo Scientific) with a standard curve created from the same stock of
654 bovine serum albumin, and then the protein lysate was stored at -80°C or on dry ice until
655 analysis.

656

657 *Cytokine assay*

658 To assess the immune response to injury in multiple species, we evaluated methods that:

659 1) used minimal sample, 2) measured local (tissue lysate) and systemic (serum) samples, 3)

660 measured several cytokines at once, 4) differentiated the magnitude and type of immune

661 response during an ear punch assay, and 5) exhibited cross-reactivity among the study species.

662 We used a custom-designed, multiplexed, sandwich ELISA array (Quansys Biosciences, Logan

663 UT). This platform meets the above requirements and the experiments can be performed in

664 multiple locations (i.e., Kentucky and Kenya) because the imager and reagents can be easily

665 transported. Importantly, the imager does not require specialized calibration after being moved,

666 and the reagents do not need remain frozen. The custom assay was designed to measure 16

667 antigens including IL-1 α , IL-1 β , IL-2, IL-4, IL-5, IL-6, IL-10, IL-12p70, IL-17, CCL2, CCL3,

668 CCL5, CSF2, IFN γ , TNF α and CXCL1.

669 Initial testing identified that antigens from serum could be quantified by diluting serum in

670 the supplied mouse specific diluent 1:1 and from tissue lysate using 5, 40, and 80 μ g total protein

671 in RIPA buffer for *M. musculus*, *A. cahirinus*, and *A. percivali*, respectively. The samples were

672 run in duplicate using a protocol modified from the manufacturer's instructions, as follows: All

673 serum samples were diluted 1:1 (serum : diluent) and all tissue samples were diluted 1:1 (RIPA +

674 lysate : mouse sample diluent) to a volume of 50 μ L per well. The diluted samples were then

675 loaded onto a new assay plate with an appropriate standard curve (1:3 to 1:59049) and four

676 blanks. Samples were incubated at 4°C for 8 hours on a plate shaker set to 500 rpm to capture

677 antigen in each well. After washing the plate 4 times with wash buffer, the primary antibody

678 cocktail was loaded and the plate was incubated at 4°C for 8 hours on a plate shaker set to 500

679 rpm to allow binding of the biotinylated detection antibodies to the captured antigens. After
680 washing the plate 4 times, streptavidin-HRP conjugated secondary antibody was loaded and the
681 plate was incubated at room temperature for 30 minutes on a plate shaker set to 500 rpm. The
682 plate was washed 8 times, chemiluminescent reagent was added, and the plate was immediately
683 imaged with a chemiluminescent plate imager set to the manufacturer recommended image
684 capture settings (Q-view imager, Quansys Biosciences).

685 We verified that cytokine concentrations derived from the Quansys multiplex array were
686 comparable between *Mus* and *Acomys* by testing for parallelism of the mouse standards with
687 *Acomys* serum and tissue lysate. We also evaluated the peptide-level similarity between *Mus* and
688 *Acomys* for each gene represented on the array. Parallelism was examined using standard
689 protocols [92, 93]. Briefly, samples from species and source were randomly pooled to provide a
690 representative cytokine concentration and were run in triplicate at serial dilutions (1:2, 1:6, 1:18,
691 1:54, and 1:162). To determine parallelism, linear regressions were calculated for samples that
692 had at least 3 dilutions above the lower limit of detection and compared the slopes to the
693 standard curve. For peptide comparisons, the *A. cahirinus* genomic and/or transcribed sequences
694 corresponding to the 16 cytokines of interest were identified by using TBLASTX with inputted
695 *M. musculus* peptide sequence into previously published spiny mouse transcriptomes [40, 94]
696 and an unpublished draft genome. The mRNA sequence was then translated and aligned to
697 peptide sequences for *M. musculus*, *Rattus norvegicus* and *Homo sapiens* using MAFFT [95, 96].
698 Total similarity and identity was calculated using the Sequence Identity and Similarity (SIAS)
699 tool (<http://imed.med.ucm.es/Tools/sias.html>).

700 Individual cytokine concentrations were obtained using image analysis software (Q-view
701 v3.09, Quansys Biosciences). First, the standard curve pixel intensity values were observed and

702 pixel intensity values greater than 60,000 were masked to remove saturated data points. Sample
703 concentrations were calculated from standard curves created by a five parameter logistic
704 regression (5PL) with \sqrt{y} weighting. The average value from each duplicate was then used for
705 subsequent analyses. If the average value was above the lower limit of detection and the pixel
706 intensity co-efficient of variation between duplicates was greater than 15%, the sample was re-
707 assayed on another plate and a new average calculated. Initially, we re-assayed tissues samples
708 below the limit of detection with a greater amount of total protein, but in most cases, additional
709 protein did not equate to quantifiable antigen, suggesting that there was a minimal amount of
710 antigen in those samples. Thus, to maximize use of the plates, we opted to quantify a greater
711 total number of samples and assayed each sample at one dilution. Antigens below the lower
712 limit of detection were recorded as “not present”, and to calculate ratios they were assigned the
713 largest value of the lower limit of detection for that antigen across all plates assayed [97].

714

715 ***Cox-2 inhibition***

716 Mm-UKY were subjected to a routine ear punch assay and randomly split into two
717 groups: A) 100 mg/kg celecoxib, a potent and specific COX-2 inhibitor or B) vehicle. A
718 Celecoxib capsule was opened and mixed into 0.5% (w/v) methyl cellulose to the appropriate
719 concentration and a 200 μ L dose was administered (100 mg active drug / kg body weight) by
720 oral gavage using a 20x30 mm gavage needle tipped with a sugar solution each morning
721 beginning 1 day before injury through 20 days after injury. Ear holes were measured and ear
722 hole area was calculated for every 5 days post injury, as previously described [40]. On D10 and
723 64 entire ears were harvested from a different set of animals and used for histology and stained
724 with Mason’s Trichrome or Picrosirius red, as previously described [40]. Re-epithelialization

725 was confirmed by the presence of a connected and complete epidermis distal to the amputation
726 plane by examining two tissue sections from the proximal and distal wound sites for each animal
727 at D10. Fibrosis was determined by quantifying the area of collagen deposition in the dermis
728 distal from the amputation plane from two sections from the proximal and distal wound sites
729 using circular polarized light microscopy and the thresholding function in Image J after
730 removing the epidermis, epidermal appendages and tissue artifacts.

731

732 *Flow Cytometry*

733 To quantify the number of CD3⁺ cells present in healing ear tissue, tissue was harvested
734 from a separate group of Mm-UKY and Ac females at D0, 1, 3, 7 and 15 using an 8 mm biopsy
735 punch. Harvested tissue from both ears was combined and a single-cell suspension was created
736 using combination of enzymatic and mechanical digestion, as previously described [15]. Total
737 cells were counted by hemacytometer and incubated with PE-conjugated-anti-CD3 (Clone 17A2,
738 BioLegend, San Diego, CA) at a concentration of 1 $\mu\text{g} / 10^6$ cells for 1 hour at room temperature,
739 washed and suspended in cell staining buffer (Cat#420201, BioLegend). Flow cytometry was
740 carried out at the University of Kentucky Flow Cytometry Core using the iCyt Synergy sorter
741 system (Sony Biotechnology Inc., San Jose, CA). Laser calibration and compensation was
742 performed for each experiment using unstained and single fluorescent control samples. Analysis
743 was done using FlowJo (Version 10, FlowJo, LLC, Ashland, OR) to identify CD3-positive
744 lymphocytes by PE fluorescence and forward- and side-scatter. The same gating strategies
745 between species were used (n = 4 or 5 animals per timepoint).

746

747 *Immunohistochemistry*

748 To identify the locations of STAT3 responsive cells and CD3+ cells, tissue sections were
749 de-paraffinized, rehydrated, and prepared for examination by light- or fluorescent-microscopy,
750 respectively. For light-microscopy, resident peroxidase was quenched by H₂O₂, antigens were
751 exposed by heat-mediated retrieval with sodium citrate buffer, pH=6.0, blocked with serum,
752 incubated with primary antibody (anti-pSTAT3, Cell Signaling Technology Cat#9145, 1:200)
753 overnight at 4°C, incubated with a horseradish peroxidase conjugated secondary (Santa Cruz
754 Biotechnology, Cat#sc-2030, 1:1000) for 1 hour at room temp, treated with 3,3'-
755 Diaminobenzidine (SK-4100, Vector Laboratories, Burlingame, CA) until a visible brown
756 precipitate was observed, counter-stained with hematoxylin, dehydrated and cover-slipped. For
757 fluorescent-microscopy, antigens were exposed by heat mediated retrieval with sodium citrate
758 buffer, pH=6.0, resident avidin and biotin was blocked, sections blocked with serum, incubated
759 with primary antibody (anti-CD3, DAKO, Cat#A0452, 1:500) overnight at 4°C, incubated with a
760 biotin conjugated secondary antibody (Vector Laboratories, Cat#PK-6101, 1:400) for 1 hour at
761 room temp, incubated with streptavidin conjugated AlexaFlour-594 (Molecular Probes,
762 Cat#S11227, 1:5,000), counter-stained with 4',6-Diamidino-2-Phenylindole, Dihydrochloride
763 (Molecular Probes, Cat#D1306, 1:10,000) and cover-slipped. Images were acquired using a
764 compound epi-fluorescence microscope (IX-51, Olympus Corporation, Tokyo, Japan) equipped
765 with a CCD camera (DP-74, Olympus Corporation) and software (cellSens v1.12, Olympus
766 Corporation).

767

768 ***Immunoblot***

769 To quantify the STAT3 response to injury, 30 or 40 µg of total protein from tissue lysate
770 was denatured and separated by SDS polyacrylamide gel electrophoresis and transferred to a

771 PVDF membrane (IB401002, Life Technologies). Membranes were cut along the 55 kDa ladder
772 marker and blocked with either 5% BSA or 5% dry skim milk in TBST for 1 hour at room
773 temperature, incubated with primary antibody (pSTAT3, Cell Signaling, Cat#9145, 1:2000;
774 ACTB, Cell Signaling, Cat#4967, 1:5000), washed, incubated with secondary antibody (Santa
775 Cruz Biotechnologies, Cat#sc-2030, 1:10,000), and visualized by chemiluminescence
776 (Cat#RPN2235, GE Healthcare) using a digital CCD camera (UVP LLC, Upland, CA). Total
777 pixel intensity was quantified using regions of interest and normalized to background and
778 uninjured tissue using ImageJ2 [98].

779

780 *Statistical Analysis*

781 To compare the baseline serum cytokine concentrations we used a one-way ANOVA and
782 Tukey-Kramer HSD posthoc tests to test for individual group differences. To compare the
783 dynamics of cytokine concentration over time in serum and tissue, a ratio of the injured
784 concentration mean to the uninjured concentration mean was calculated for each cytokine by
785 group (Mm-UKY, Mm-Kenya, Mm-Wild, Ac and Ap) and time point (D1-D20). To normalize
786 cytokine fold-change distributions, data were log transformed. A two-way ANOVA was then
787 used to test for effects of time and group on tissue and serum separately. Pairwise comparisons
788 were tested using the Tukey-Kramer HSD method. In the event that several undetected values
789 existed at an individual timepoint and log transformed data still did not meet normality, we used
790 non-parametric Wilcoxon rank sum tests with Steel Dwass post-hoc tests for pairwise
791 comparisons. Datasets for which non-parametric analyses were performed are indicated in figure
792 legends.

793 To compare the immunoblot data, pixel intensity was calculated for the bands of interest
794 using an identical sized region of interest with ImageJ [98]. The pixel intensity of pSTAT3 was
795 normalized to ACTB and a two-way ANOVA with time and species was used to compare values
796 and pairwise comparisons were made using the Tukey-Kramer HSD method. To compare the
797 flow cytometry results, we used a two-way ANOVA with time and species on log-transformed
798 data and pairwise comparisons were made using the Tukey-Kramer HSD method. To compare
799 the ear-hole closure rate between control and celecoxib-treated animals we used a repeated-
800 measures ANOVA and cubic regression, as previously published [40]. To compare the ear-hole
801 area and area of tissue positive for Picrosirius, we used a student's t-test. All statistical tests
802 were done using JMP Pro 14 (SAS Institute Inc., Cary, NC) or Prism 5.0 (GraphPad Software,
803 Inc., San Diego, CA). A *P*-value < 0.05 was used to determine significance for each test. All
804 graphs were created in Prism 5.0 and placed into figures using Illustrator CS5 (Adobe Systems,
805 Inc. San Jose, CA).

806

807 **SUPPLEMENTAL INFORMATION**

808 **Supplemental Table 1:** One-way ANOVA analyses of log-transformed uninjured serum data.
809 Groups listed in comparison column represent groups for which data was quantified and could be
810 compared. *P*-values indicate where at least one group is significantly different from another
811 group. Tukey-Kramer HSD post-hoc tests were used for pairwise comparisons are summarized
812 in Figure 1A (See Supplemental File).

Antigen	Comparison	N	F	<i>P</i> -value

827 **Supplemental Table 4:** One-way ANOVA analysis of tissue cytokine data to test for an effect of
 828 group at D1, 2, 10 and 20. *P*-values indicate where at least one group is significantly different
 829 from another group. Tukey-Kramer HSD post-hoc tests were used for pairwise comparisons and
 830 are summarized in Figure 3 (See Supplemental File).
 831

Antigen	Comparison	N	Day	F-Ratio	<i>P</i> -value
IL-1 β	All groups		1	5.39	0.002*
			2	32.52	<0.001*
			10	20.70	<0.001*
			20	19.05	<0.001*
IL-4	All groups		1	9.71	<0.001*

837

838

839 **Supplemental Figure 1 Comparison of parallelism for cytokine assays demonstrates ability**
840 **to quantify cytokines across three species.** Serial dilution of serum (triangles, solid lines) and
841 tissue lysate (squares, dashed lines) shows similar negative slopes for *M. musculus* (green), *A.*
842 *percivali* (red) and *A. cahirinus* (blue) compared to the standard (black, circles, solid line). Data
843 represent the mean for duplicates and lines are linear regressions calculated from all data that
844 was above the lower limit of detection.

845
846 **Supplemental Figure 2 Comparisons of amino acid sequence alignments for antigens in**
847 **study.** Predicted amino acid sequence was translated from mRNA (*A. cahirinus*) or obtained
848 from NCBI (*H. sapiens*, *M. musculus*, *R. rattus*) and aligned together using MAFFT. Figures
849 were created using BOXSHADE where solid black shading is equivalent, gray shading is similar
850 and no shading is dissimilar.

851

852 **Supplemental Files**

853

854 Supplemental File 1 contains summary tables of post-hoc multiple comparison tests used in
855 Figure 1B, Figure 2 and Figure 3.

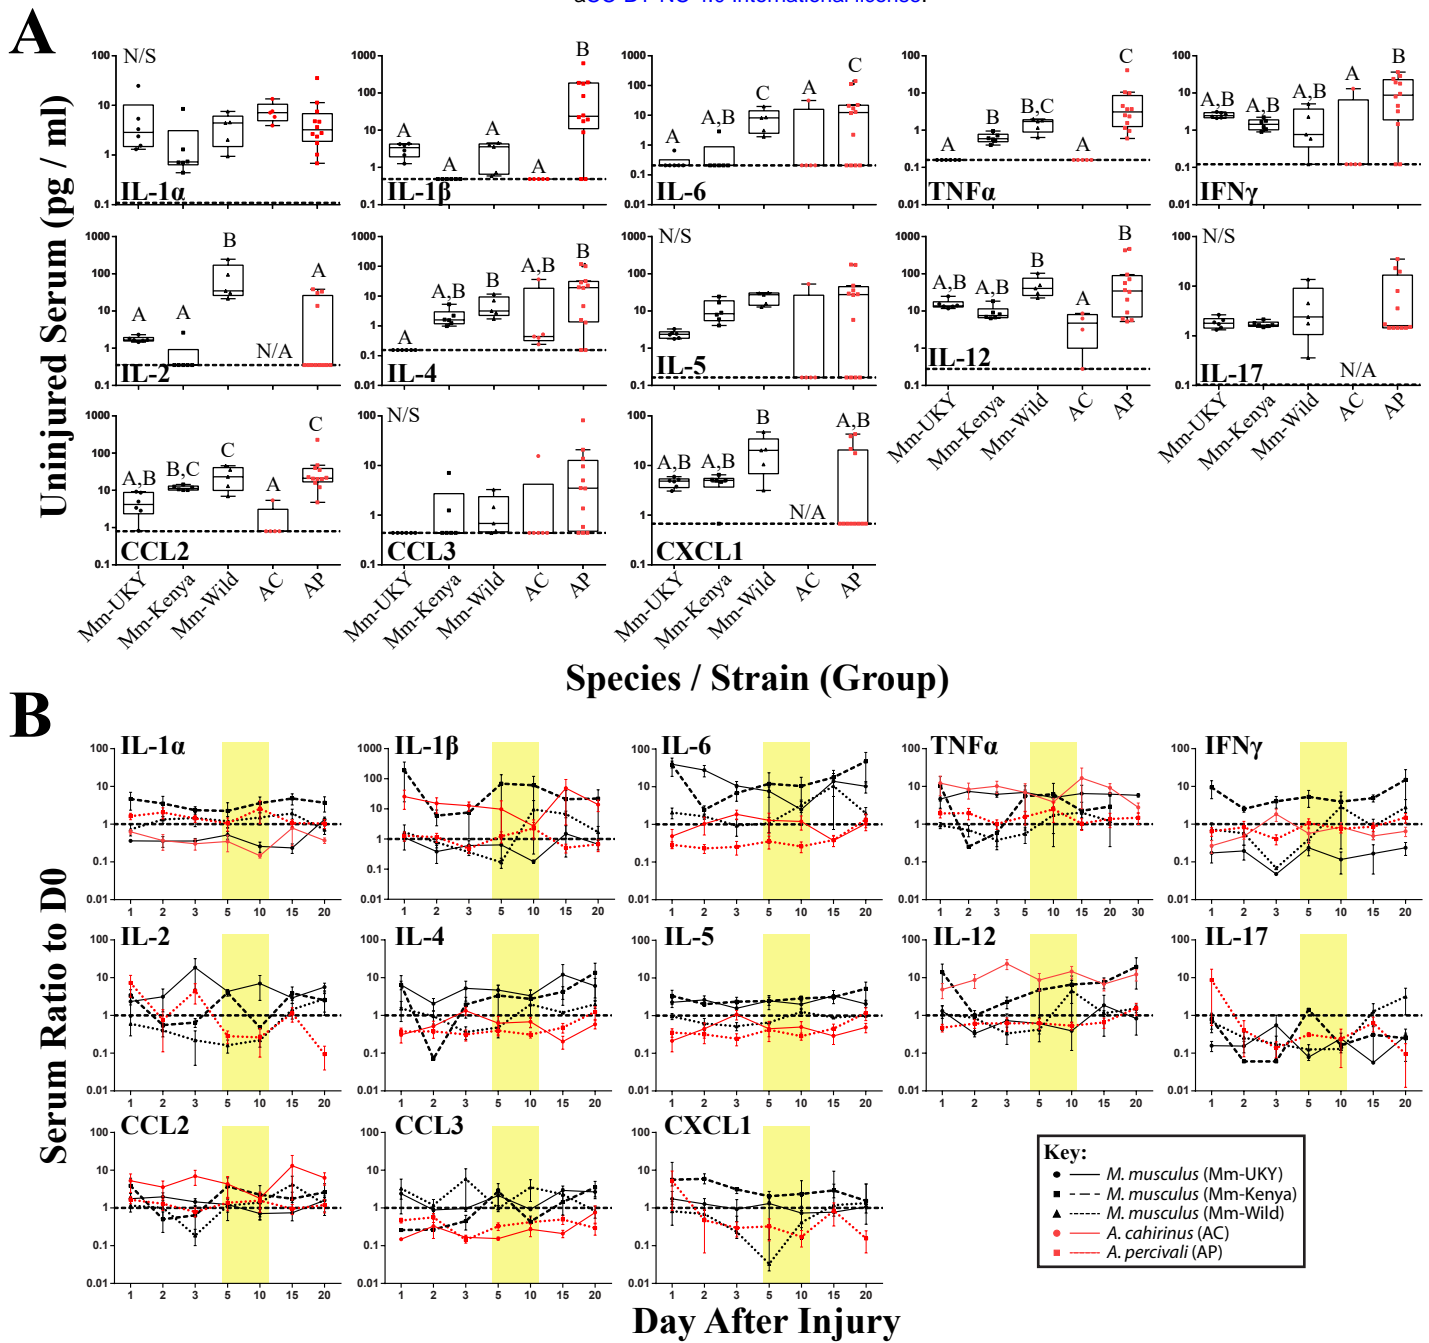

Figure 1 Ability to regenerate and immunity-status are associated with a specific systemic immune profile and immune response to injury. (a) Comparison of cytokine concentrations in serum from uninjured animals showed higher concentrations of IL-4, IL-6, CCL2 and TNF α in wild-caught animals compared to laboratory-reared animals indicated that wild animals have a “primed” immune system. No difference was found between non-regenerators (Mm-UKY, Mm-Kenya and Mm-Wild) and regenerators (Ac and Ap). Data represent box and whiskers with median, interquartile range and individual data points. N/A denotes concentrations could not be quantified in any animal of the group. The dashed line in each graph represents the lower limit of detection for the specific cytokine. N/S denotes P>0.05 for One-way ANOVA (See Supplemental Table 1) and different letters above the data denotes P \leq 0.05 for Tukey-Kramer pairwise comparisons (See Supplemental File). (b) The change in systemic cytokines compared to D0 over 20 days after ear hole punch. A naïve immune system response (solid lines) was consistent with increased IL-2 and TNF α , and decreased IL-1 α compared to a primed response (intermittent lines) (See Supplemental Table 2). Non-regenerators (black) showed increases in IL-5, IL-6, IL-17, CCL3 and CXCL1 compared to regenerators (red). Data represent mean and S.E.M. for at least n=5 animals per timepoint. The dashed line at Y=1 represents no change compared to D0 and the yellow boxes represent the inflammation resolution window.

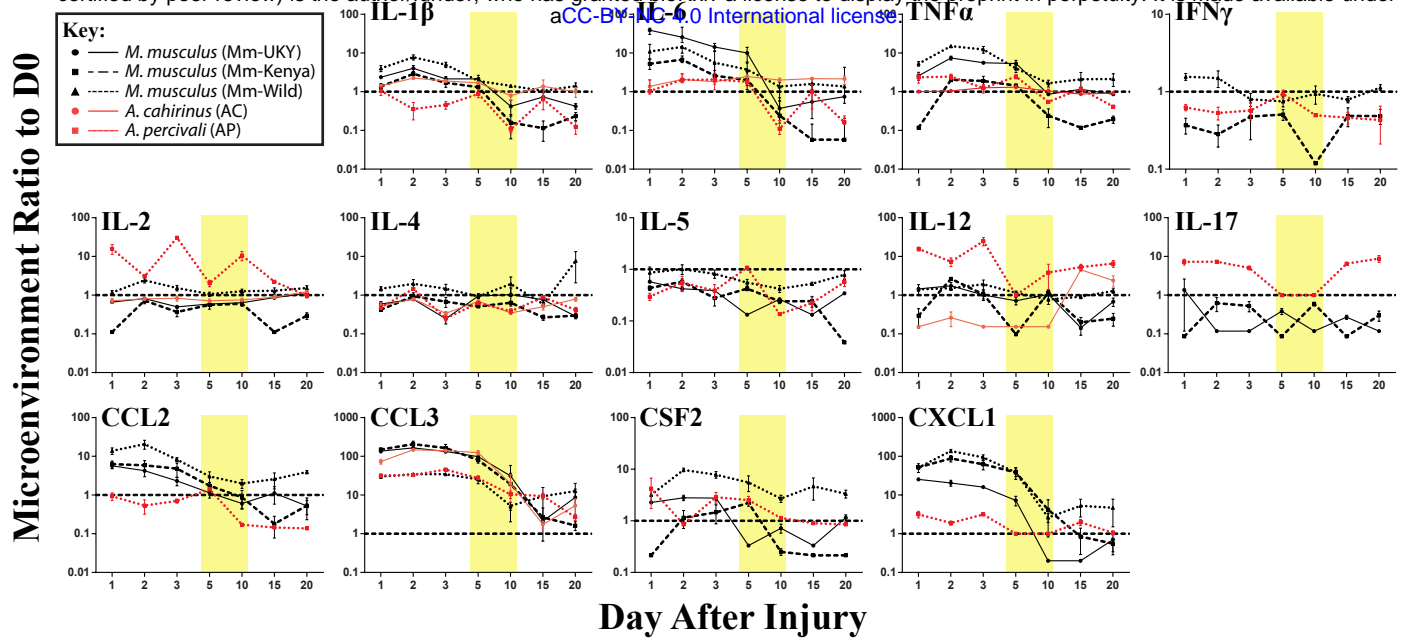

Figure 2 The tissue microenvironment is dynamic, and the ability to regenerate is associated with a specific immune response to injury. The comparison of the change in cytokines from tissue lysate compared to D0 over 20 days after ear hole punch. All cytokines varied over time and between groups (See Supplemental Table 3). There was a stronger increase in CCL3 a muted increase for IL-12 and CXCL1 in immune-naïve (solid lines) compared to immune-primed animals (intermittent lines). Non-regenerators (black) had stronger increases for IL-6, CCL2 and CXCL1 compared to regenerators (red). Additionally, IL-17 decreased in non-regenerators and increased in regenerators. Data represent mean and S.E.M. for at least n=5 animals per species per timepoint. The dashed line at Y=1 represents no change compared to D0 and the yellow boxes represent the inflammation resolution window.

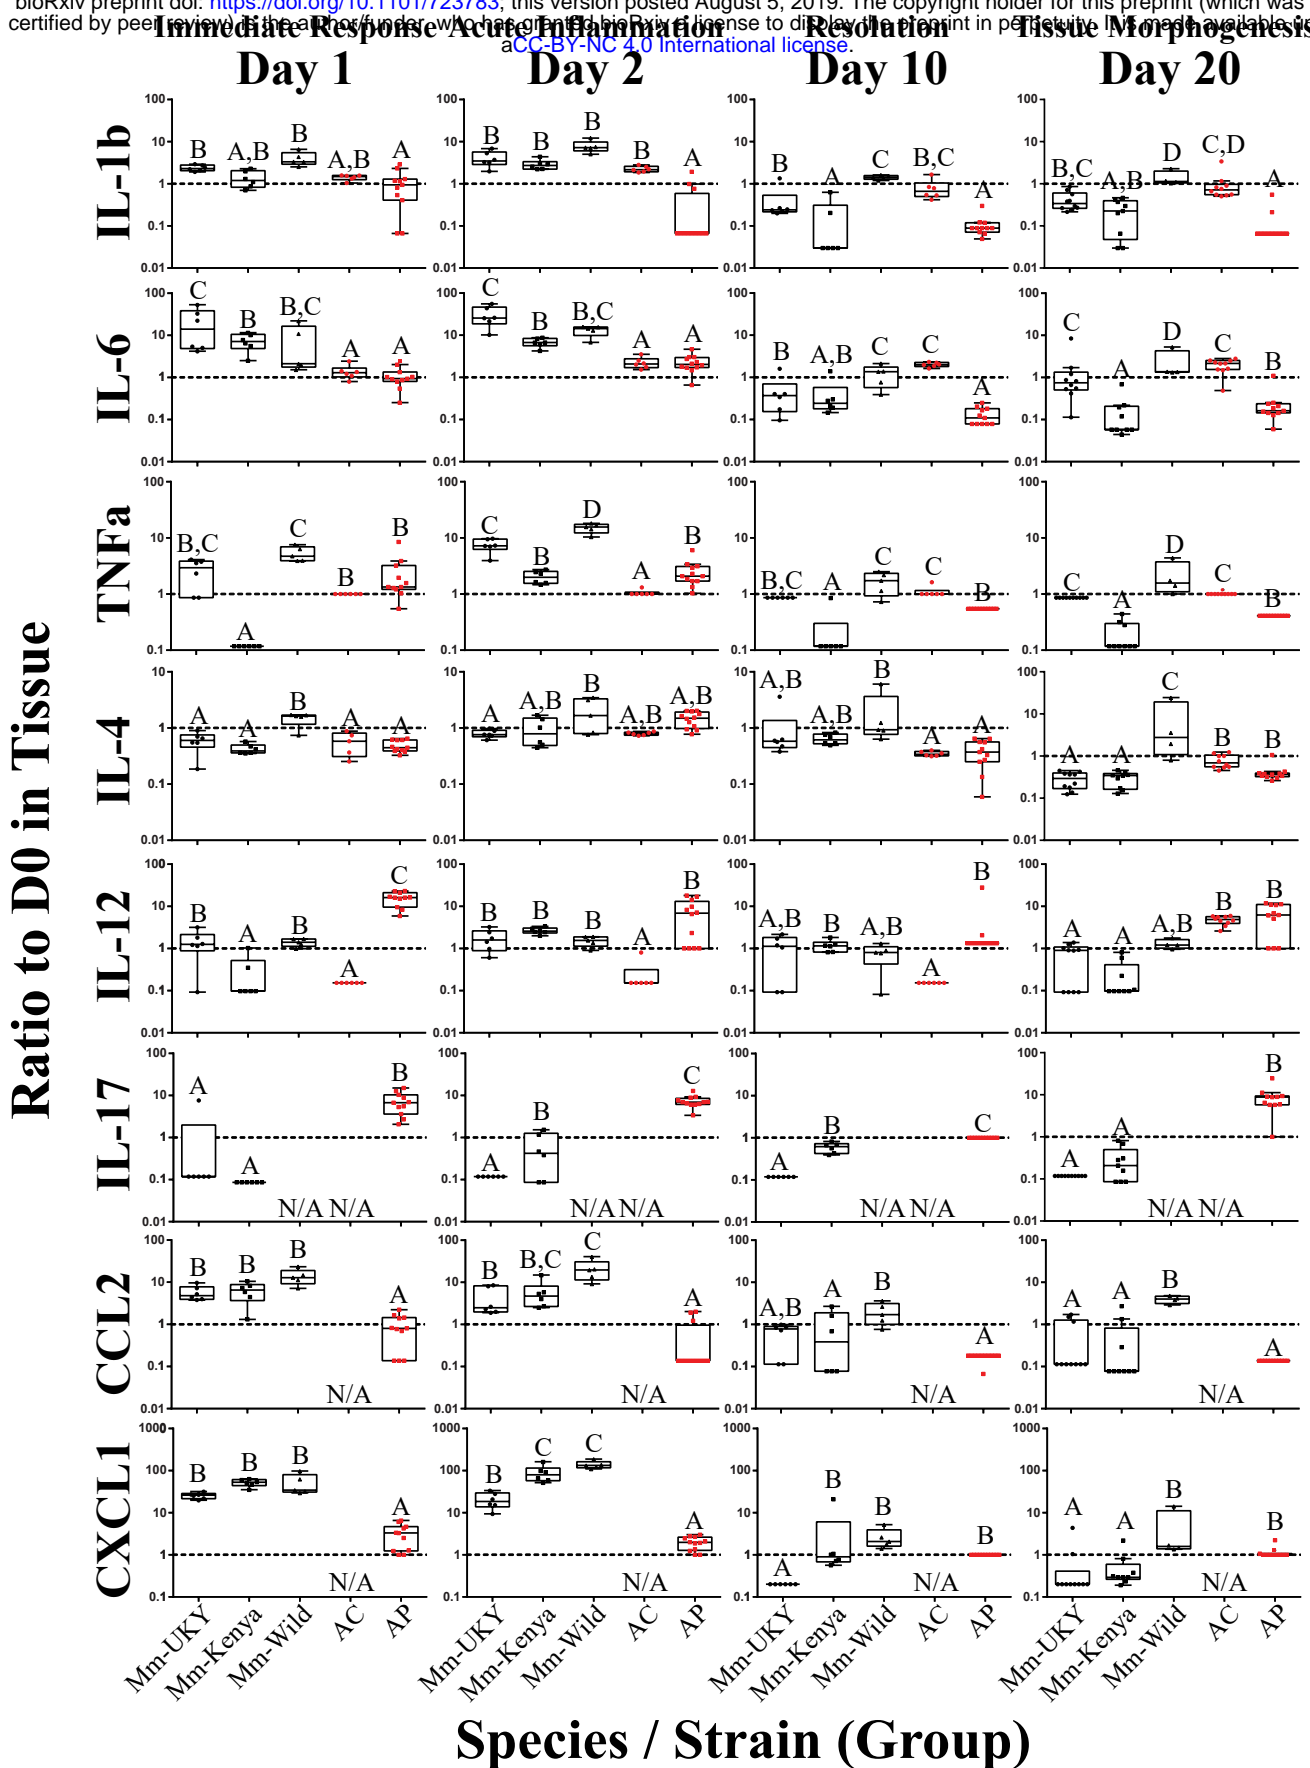

Figure 3 Regeneration is associated with specific temporal cytokine responses in the tissue microenvironment. The comparison of the change in cytokines from tissue lysate compared to baseline. Non-regenerators (Mm-UKY, Mm-Kenya, and Mm-Wild: Black) show a stronger response compared to regenerators (Ac and Ap: Red) for several inflammatory cytokines during the immediate response, acute inflammatory phase. These differences mostly resolved at day 10 and 20. In contrast, regenerators showed a stronger IL-12 and IL-17 response during tissue morphogenesis. Data represent box and whiskers with median, interquartile range and individual data points. N/A denotes concentrations could not be quantified. The dashed line at Y=1 represents no change compared to D0. Each graph showed P<0.05 for effect of group using a One-way ANOVA on log-transformed data (See Supplemental Table 4) and different letters above each group denotes P<0.05 for Tukey-Kramer pairwise comparisons (See Supplemental File).

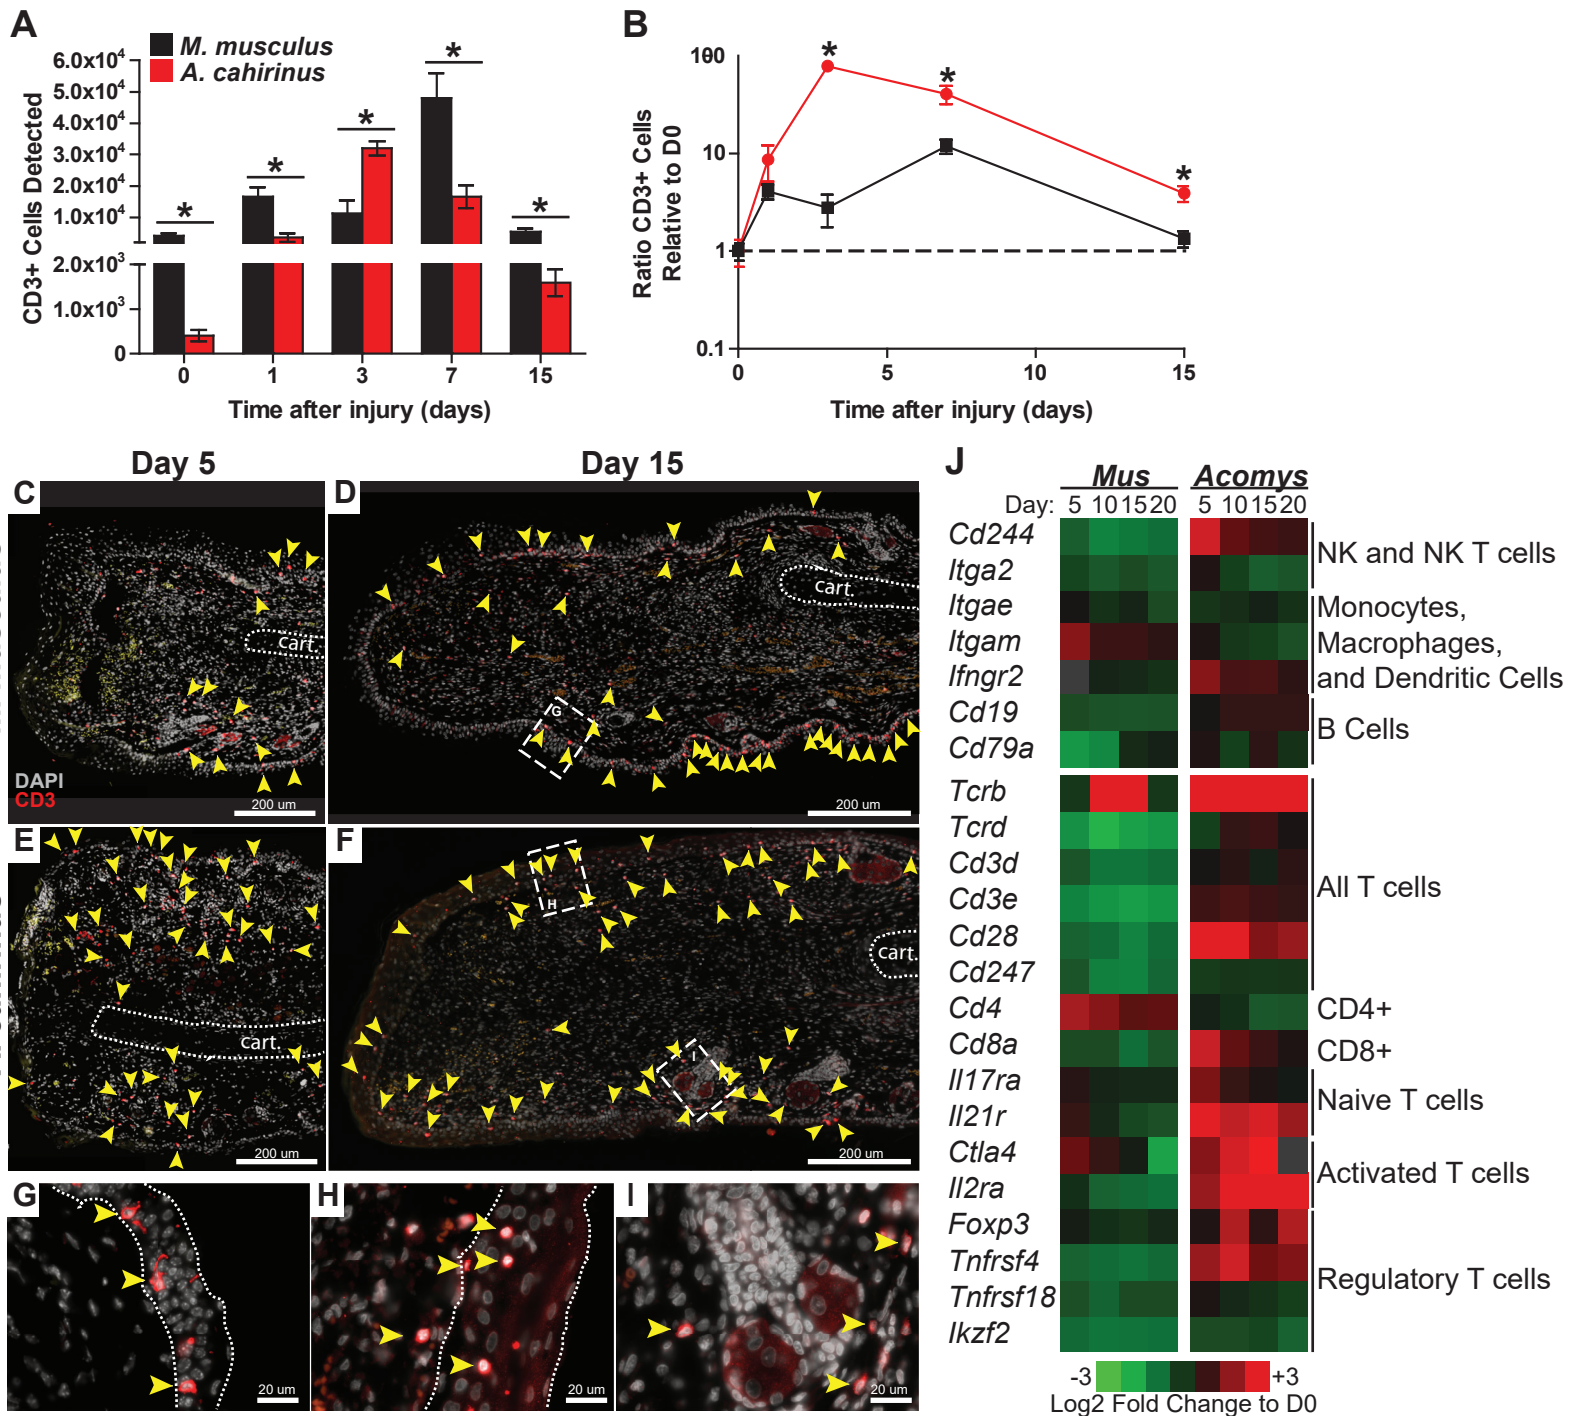

Figure 4 The regeneration microenvironment is primed by greater T cell influx and TREG signature.

(A) Comparison of total CD3⁺ cells quantified by flow cytometry from disassociated ear pinna and (B) the ratio relative to uninjured tissue for *M. musculus* (black) and *A. cahirinus* (red). Data represent mean and S.E.M. and n=4 or 5. An * denotes P<0.05 for pairwise comparison within the day between species for Holm-Sidak posthoc test.

(C-I) Representative immunohistochemistry for CD3 (red) counterstained with DAPI (gray) at the proximal wound margin (amputation plane can be determined from the end of the cartilage—indicated by the dotted line) from D5 and D15 after injury of *M. musculus* (C, D) and *A. cahirinus* (E, F). More T cells (yellow arrowhead) were present throughout the wound bed and were mainly found in the dermis of *A. cahirinus* compared to *M. musculus*. The T cells associated with epidermis (boundaries indicated by the dotted line) tended to be spindle-like in *M. musculus* (G), while rounded in *A. cahirinus* (H). The dermal T cells in *A. cahirinus* also tended to be in close proximity to regenerating epidermal appendages (I). N=4 and bar equals 200 μ m (C-F) or 20 μ m (G-I). (J) Heatmap of differential gene expression compared to uninjured tissue suggests that the regeneration microenvironment contains a substantial NK, CD8⁺ and TREG cell response while fibrotic repair has a CD4⁺ cell response. Data comes from a previously published analysis [34].

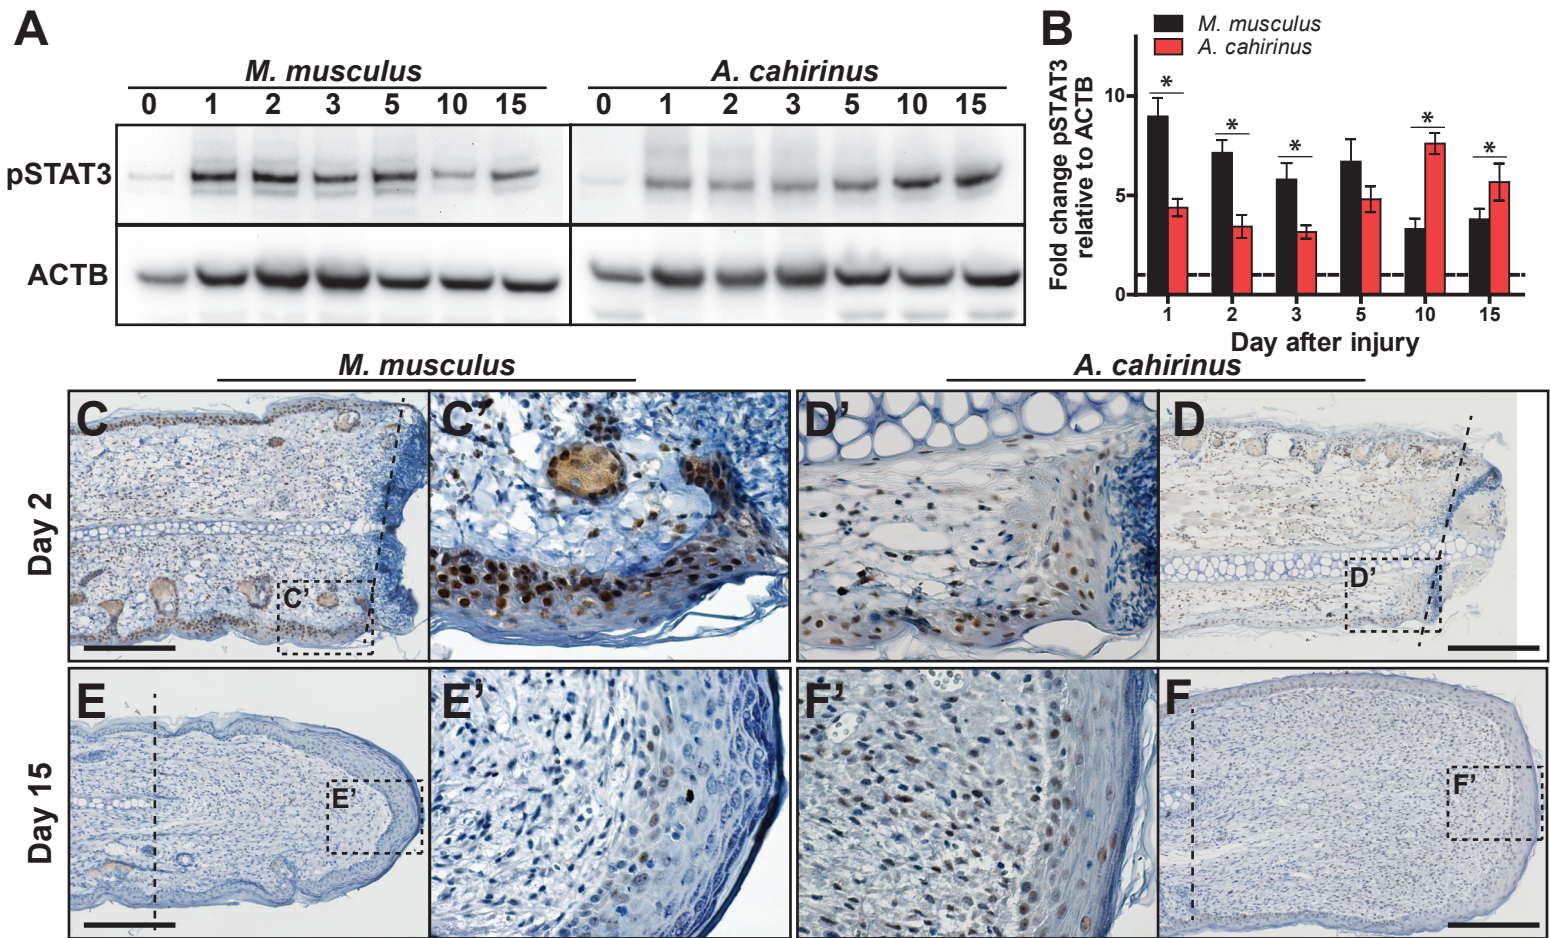

Figure 5 Postponed STAT3 activation in the blastema is associated with regeneration. (A-B) Comparison of representative immunoblots for pSTAT3 and ACTB for indicated time and species from injured tissue homogenate from ear-hole punch assay (A). Fibrotic repair is associated with strong early STAT3 activation while regeneration is associated with a weak early and strong postponed activation (B). Data represent mean fold change of pSTAT3 intensity normalized to ACTB intensity and relative to D0 and S.E.M. n=4 individuals per time point and species (B). (C-F) Representative images for immunohistochemistry for pSTAT3 (Brown) counterstained with hematoxylin (Blue) for *M. musculus* (C, C', E and E') and *A. cahirinus* (D, D', F and F') at the indicated time points. On D2 after injury, nearly every epidermal cell in *M. musculus* was positive compared to about half in *A. cahirinus* (C, D). On D15 after injury, only a small population of epidermal cells in *M. musculus* were positive compared to about half in *A. cahirinus* (E, F). Additionally, about half of the cells in the forming blastema remain positive at D15. Data represent n=3, and bar equals 200 μ m.

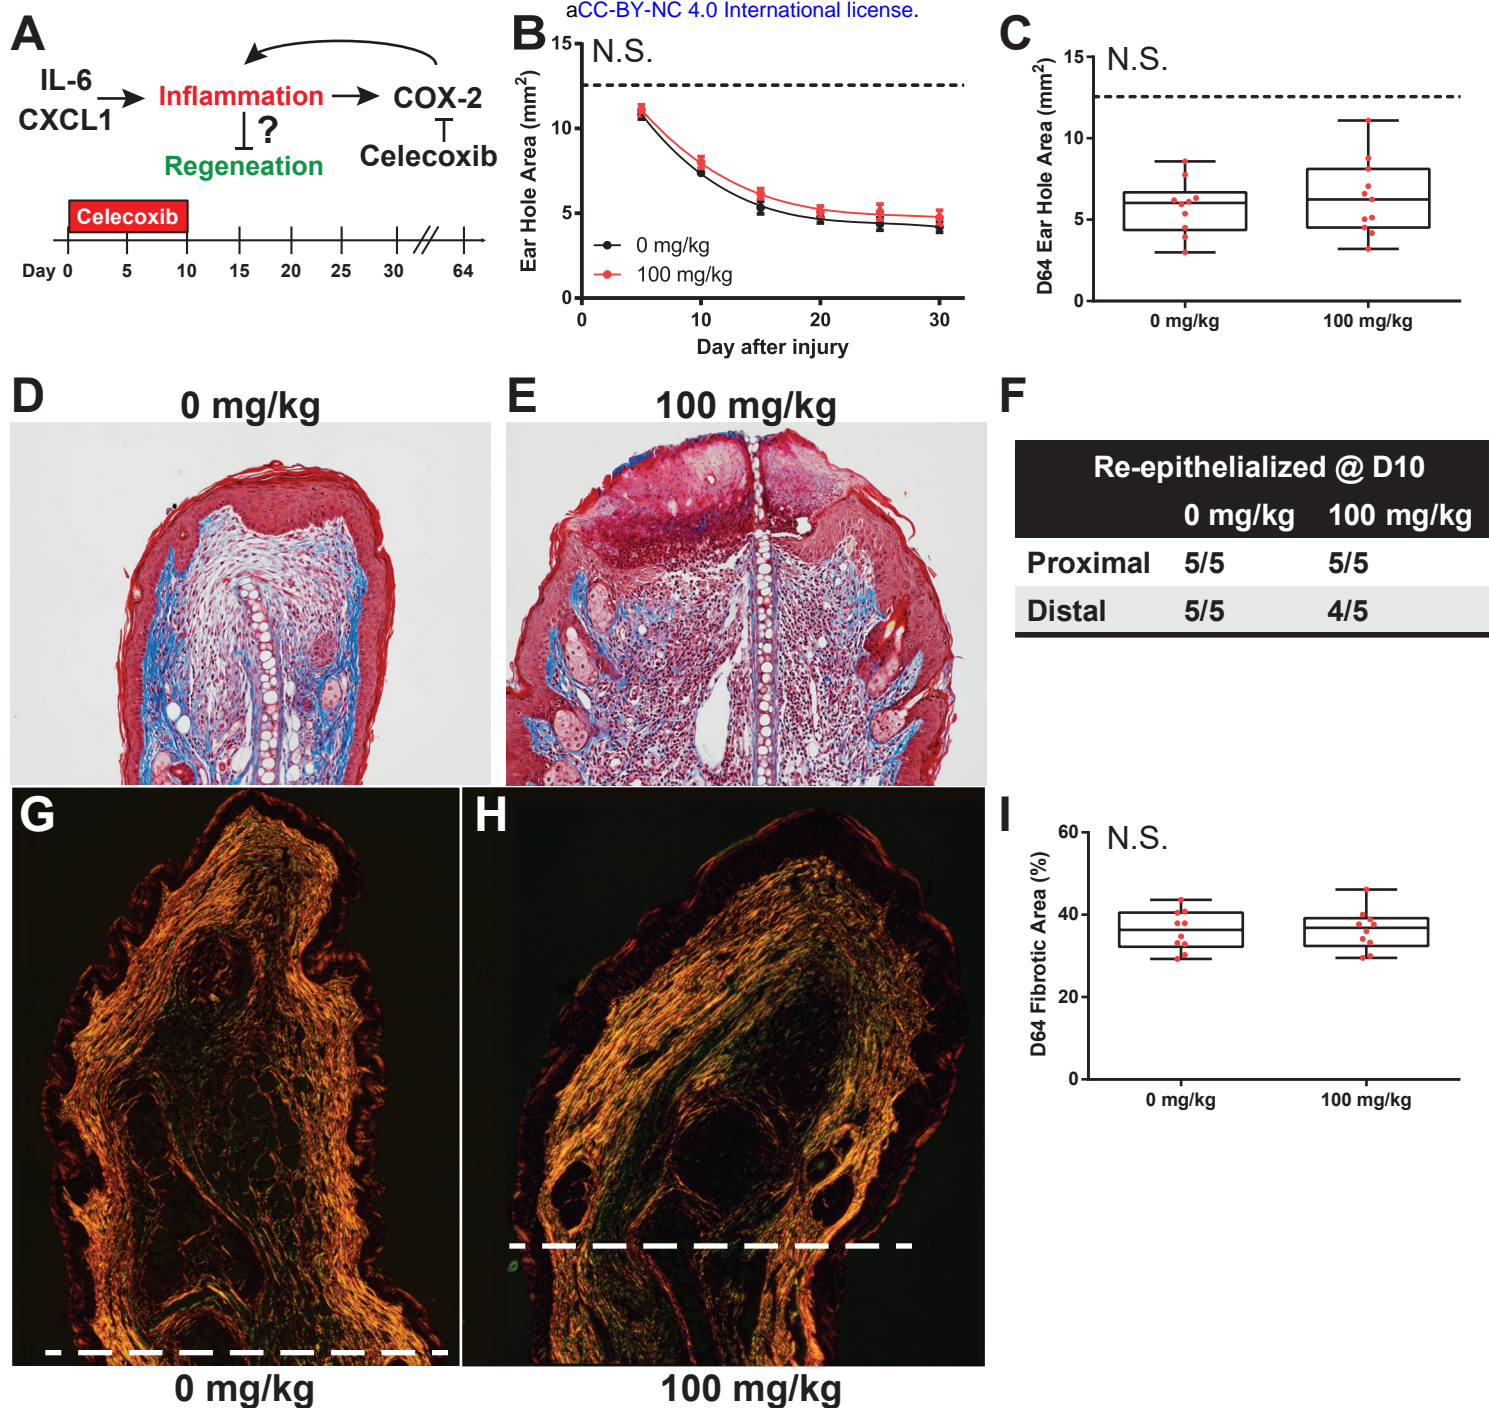

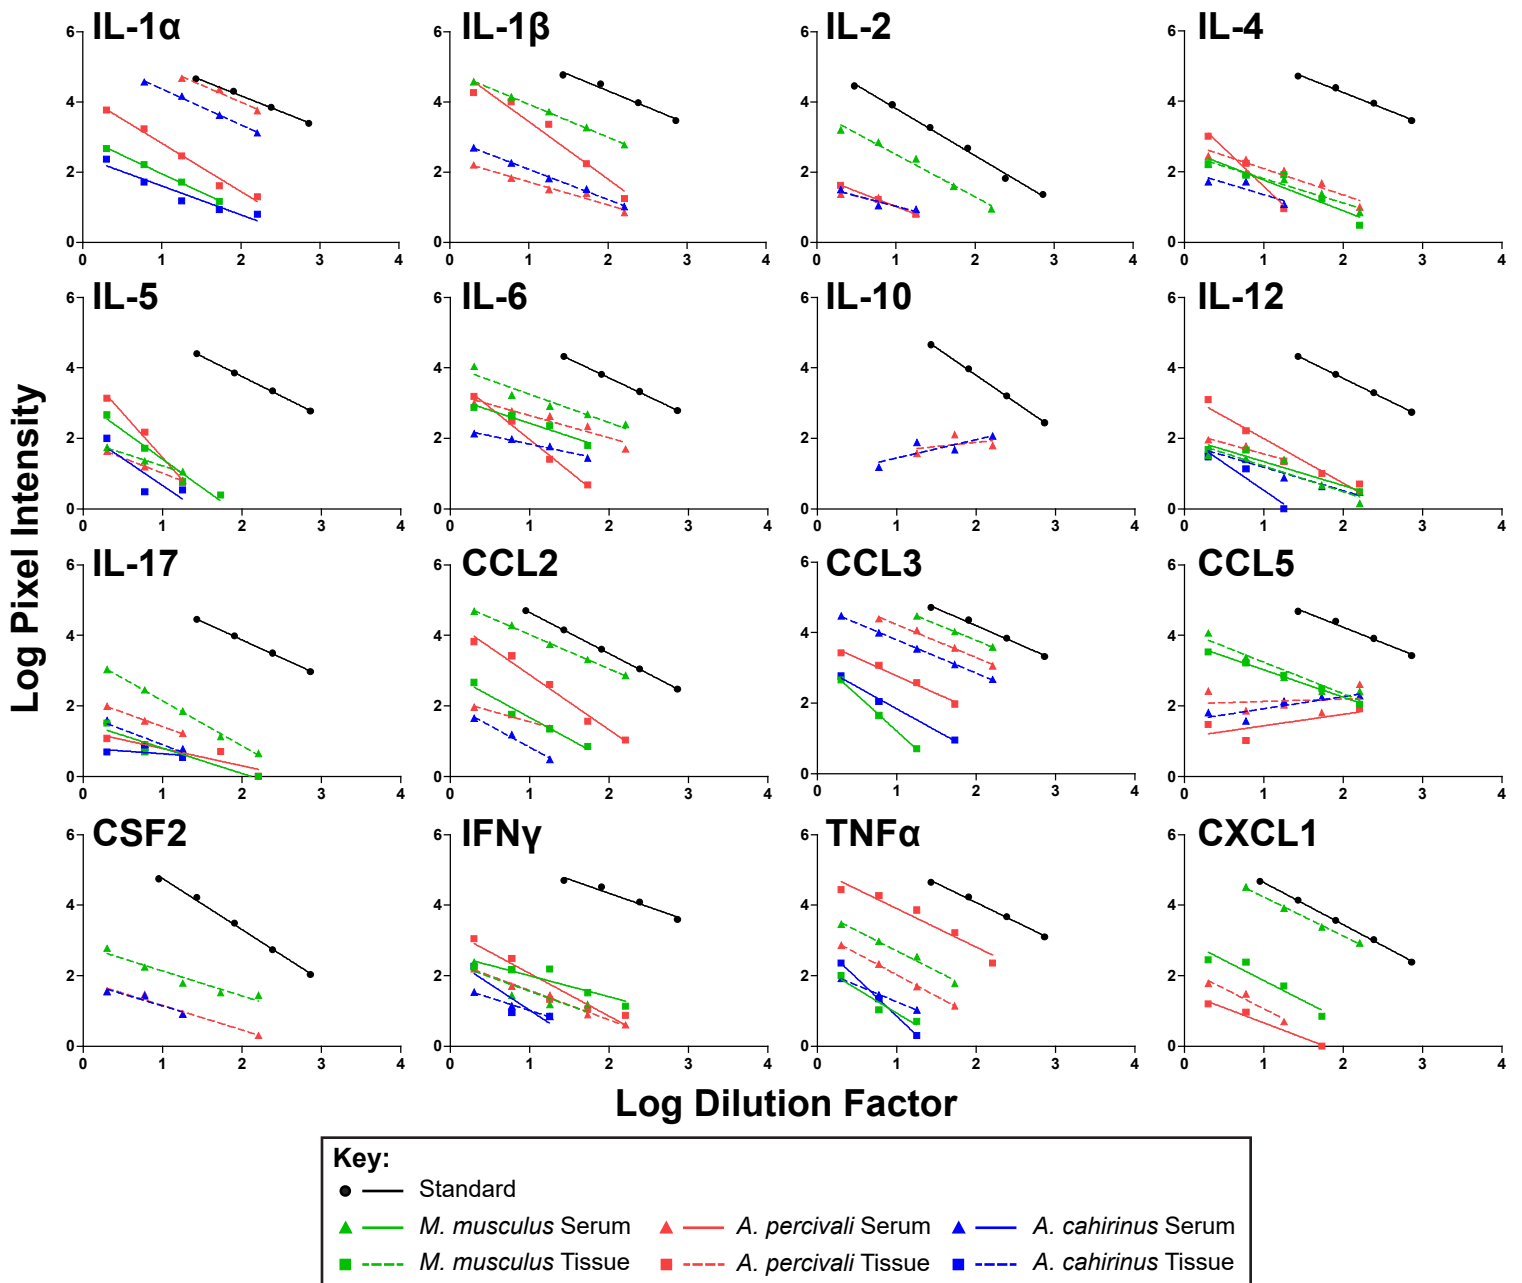

Figure 6 COX-2 Inhibition does not liberate regeneration in *M. musculus*.

(A) Celecoxib treatment during the first 10 days of injury reduces secondary inflammation caused by IL-6 and CXCL1. (B-C) Celecoxib treatment did not affect the rate of ear-hole closure from D5 to D30 (B), or ear-hole area at D64 (C). (D-F) Mason's trichrome stain on D10 ear tissue from control (D) and treatment (E) showed 20% of the distal injury plane from treated ears were not re-epithelialized, while 100% of control treated ears and the proximal injury plane were re-epithelialized (F). (G-I) Picro-sirius stain on D64 ear tissue from control (G) and treatment (H) showed no difference in the total collagen fibrotic area distal to the amputation plane (I). N.S. indicates not significant for comparison between groups. Data represent mean \pm S.E.M. and the lines represent cubic regression for $n=10$ per treatment (B), OR individual data (red dots) and median and interquartile range for $n=10$ per treatment (C, I).

Supplemental Figure 1 Comparison of parallelism for cytokine assays demonstrates ability to quantify cytokines across three species. Serial dilution of serum (triangles, solid lines) and tissue lysate (squares, dashed lines) shows similar negative slopes for *M. musculus* (green), *A. percivali* (red) and *A. cahirinus* (blue) compared to the standard (black, circles, solid line). Data represent the mean for duplicates and lines are linear regressions calculated from all data that was above the lower limit of detection.
